BFD Index				. 220

1 Introduction

BFD is a package which allows applications to use the same routines to operate on object les whatever the object le format. A new object le format can be supported simply by creating a new BFD back end and adding it to the library.

BFD is split into two parts: the front end, and the back ends (one for each object le format).

- The front end of BFD provides the interface to the user. It manages memory and various canonical data structures. The front end also decides which back end to use and when to call back end routines.
- The back ends provide BFD its view of the real world. Each back end provides a set of calls which the BFD front end can use to maintain its canonical form. The back ends also may keep around information for their own use, for greater e ciency.

1.1 History

One spur behind BFD was the desire, on the part of the GNU 960 team at Intel Oregon, for interoperability of applications on their COFF and b.out le formats. Cygnus was providing GNU support for the team, and was contracted to provide the required functionality.

The name came from a conversation David Wallace was having with Richard Stallman about the library: RMS said that it would be quite hard | David said \BFD". Stallman was right, but the name stuck.

```
return bfd_count_sections (abfd);
}
```

The abstraction used within BFD is that an object le has:

- a header,
- a number of sections containing raw data (see Section 2.6 [Sections], page 24),
- a set of relocations (see Section 2.10 [Relocations], page 55), and
- some symbol information (see Section 2.7 [Symbols], page 44).

Also, BFDs opened for archives have the additional attribute of an index and contain subordinate BFDs. This approach is ne for a.out and co , but loses e ciency when applied to formats such as S-records and IEEE-695.

1.3 What BFD Version 2 Can Do

When an object le is opened, BFD subroutines automatically determine the format of the input object le. They then build a descriptor in memory with pointers to routines that will be used to access elements of the object le's data structures.

As di erent information from the object les is required, BFD reads from di erent sections of the le and processes them. For example, a very common operation for the linker is processing symbol tables. Each BFD back end provides a routine for converting between the object le's representation of symbols and an internal canonical format. When the linker asks for the symbol table of an object le, it calls through a memory pointer to the routine from the relevant BFD back end which reads and converts the table into a canonical form. The linker then operates upon the canonical form. When the link is nished and the linker writes the output le's symbol table, another BFD back end routine is called to take the newly created symbol table and convert it into the chosen output format.

1.3.1 Information Loss

Information can be lost during output. The output formats supported by BFD do not provide identical facilities, and information which can be described in one form has nowhere to go in another format. One example of this is alignment information in b. out. There is nowhere in an a. out format le to store alignment information on the contained data, so when a le is linked from b. out and an a. out image is produced, alignment information will not propagate to the output le. (The linker will still use the alignment information internally, so the link is performed correctly).

Another example is COFF section names. COFF les may contain an unlimited number of sections, each one with a textual section name. If the target of the link is a format which does not have many sections (e.g., a. out) or has sections without names (e.g., the Oasys format), the link cannot be done simply. You can circumvent this problem by describing the desired input-to-output section mapping with the linker command language.

Information can be lost during canonicalization. The BFD internal canonical form of the external formats is not exhaustive; there are structures in input formats for which there is no direct representation internally. This means that the BFD back ends cannot maintain all possible data richness through the transformation between external to internal and back to external formats.

This limitation is only a problem when an application reads one format and writes another. Each BFD back end is responsible for maintaining as much data as possible, and the internal BFD canonical form has structures which are opaque to the BFD core, and exported only to the back ends. When a le is read in one format, the canonical form is generated for BFD and the application. At the same time, the back end saves away any information which may otherwise be lost. If the data is then written back in the same format, the back end routine will be able to use the canonical form provided by the BFD core as well as the information it prepared earlier. Since there is a great deal of commonality between back ends, there is no information lost when linking or copying big endian COFF to little endian COFF, or a. out to b. out. When a mixture of formats is linked, the information is only lost from the les whose format di ers from the destination.

1.3.2 The BFD canonical object-file format

The greatest potential for loss of information occurs when there is the least overlap between the information provided by the source format, that stored by the canonical format, and that needed by the destination format. A brief description of the canonical form may help you understand which kinds of data you can count on preserving across conversions.

files

Information stored on a per- le basis includes target machine architecture, particular implementation format type, a demand pageable bit, and a write protected bit. Information like Unix magic numbers is not stored here | only the magic numbers' meaning, so a ZMAGIC le would have both the demand pageable bit and the write protected text bit set. The byte order of the target is stored on a per- le basis, so that big- and little-endian object les may be used with one another.

sections

Each section in the input le contains the name of the section, the section's original address in the object le, size and alignment information, various ags, and pointers into other BFD data structures.

symbols

Each symbol contains a pointer to the information for the object le which originally de ned it, its name, its value, and various ag bits. When a BFD back end reads in a symbol table, it relocates all symbols to make them relative to the base of the section where they were de ned. Doing this ensures that each symbol points to its containing section. Each symbol also has a varying amount of hidden private data for the BFD back end. Since the symbol points to the original le, the private data format for that symbol is accessible. Id can operate on a collection of symbols of wildly di erent formats without problems.

Normal global and simple local symbols are maintained on output, so an output le (no matter its format) will retain symbols pointing to functions and to global, static, and common variables. Some symbol information is not worth retaining; in a. out, type information is stored in the symbol table as long symbol names. This information would be useless to most COFF debuggers; the linker has command line switches to allow users to throw it away.

There is one word of type information within the symbol, so if the format supports symbol type information within symbols (for example, COFF, IEEE, Oasys) and the type is simple enough to t within one word (nearly everything but aggregates), the information will be preserved.

relocation level

Each canonical BFD relocation record contains a pointer to the symbol to relocate to, the o set of the data to relocate, the section the data is in, and a pointer to a relocation type descriptor. Relocation is performed by passing messages through the relocation type descriptor and the symbol pointer. Therefore, relocations can be performed on output data using a relocation method that is only available in one of the input formats. For instance, Oasys provides a byte relocation format. A relocation record requesting this relocation type would point indirectly to a routine to perform this, so the relocation may be performed on a byte being written to a 68k COFF le, even though 68k COFF has no such relocation type.

line numbers

Object formats can contain, for debugging purposes, some form of mapping between symbols, source line numbers, and addresses in the output le. These addresses have to be relocated along with the symbol information. Each symbol with an associated list of line number records points to the rst record of the list. The head of a line number list consists of a pointer to the symbol, which allows nding out the address of the function whose line number is being described. The rest of the list is made up of pairs: o sets into the section and line numbers. Any format which can simply derive this information can pass it successfully between formats (COFF, IEEE and Oasys).

2 BFD Front End

2.1 typedef bfd

A BFD has type bfd; objects of this type are the cornerstone of any application using BFD. Using BFD consists of making references though the BFD and to data in the BFD.

Here is the structure that de nes the type bfd. It contains the major data about the le and pointers to the rest of the data.

```
enum bfd_direction
    no\_direction = 0,
    read_direction = 1,
   write_direction = 2,
    both_direction = 3
  };
enum bfd_plugin_format
   bfd_pl ugi n_unknown = 0,
    bfd plugin yes = 1,
   bfd_plugin_no = 2
  };
struct bfd_build_id
    bfd_size_type size;
    bfd_byte data[1];
  };
struct bfd
  /* The filename the application opened the BFD with. */
 const char *filename:
  /* A pointer to the target jump table. */
 const struct bfd_target *xvec;
  /* The IOSTREAM, and corresponding IO vector that provide access
     to the file backing the BFD. */
 void *iostream;
 const struct bfd iovec *iovec;
  /* The caching routines use these to maintain a
     least-recently-used list of BFDs. */
 struct bfd *Iru_prev, *Iru_next;
```

```
/* When a file is closed by the caching routines, BFD retains
    state information on the file here... */
 ufile_ptr where;
 /* File modified time, if mtime_set is TRUE. */
 long mtime;
 /* A unique identifier of the BFD */
 unsigned int id;
  /* The format which belongs to the BFD. (object, core, etc.) */
 ENUM BITFIELD (bfd format) format: 3;
 /* The direction with which the BFD was opened. */
 ENUM_BITFIELD (bfd_direction) direction : 2;
 /* Format_specific flags. */
 flagword flags: 20;
 /* Values that may appear in the flags field of a BFD. These also
    appear in the object_flags field of the bfd_target_structure, where
    they indicate the set of flags used by that backend (not all flags
    are meaningful for all object file formats) (FIXME: at the moment,
    the object_flags values have mostly just been copied from backend
    to another, and are not necessarily correct). */
#define BFD NO FLAGS
                                    0x0
 /* BFD contains relocation entries. */
#define HAS_RELOC
 /* BFD is directly executable.
#define EXEC P
                                    0x2
 /* BFD has line number information (basically used for F_LNNO in a
    COFF header). */
#define HAS LINENO
                                    0x4
 /* BFD has debugging information. */

```

```
static inline bfd_boolean
bfd_set_cacheable (bfd * abfd, bfd_boolean val)
{
  abfd->cacheable = val;
  return TRUE;
}
```

2.2 Error reporting

Most BFD functions return nonzero on success (check their individual documentation for precise semantics). On an error, they call bfd_set_error to set an error condition that callers can check by calling bfd_get_error. If that returns bfd_error_system_call, then check errno.

The easiest way to report a BFD error to the user is to use bfd_perror.

2.2.1 Type bfd_error_type

The values returned by bfd_get_error are de ned by the enumerated type bfd_error_type.

```
typedef enum bfd_error
 bfd_error_no_error = 0,
 bfd_error_system_call,
 bfd_error_invalid_target,
 bfd_error_wrong_format,
 bfd_error_wrong_object_format,
  bfd error invalid operation,
  bfd_error_no_memory,
 bfd_error_no_symbols,
 bfd_error_no_armap,
 bfd_error_no_more_archi ved_files,
  bfd error mal formed archive,
 bfd_error_missing_dso,
 bfd_error_file_not_recognized,
  bfd_error_file_ambi quously_recognized,
  bfd_error_no_contents,
 bfd error nonrepresentable section,
  bfd error no debug section,
  bfd error bad value,
  bfd_error_file_truncated,
 bfd_error_file_too_big,
 bfd error on input,
  bfd_error_i nval i d_error_code
bfd_error_type;
```

2.2.1.1 bfd_get_error

Synopsis

```
bfd_error_type bfd_get_error (void);
```

Description

Return the current BFD error condition.

2.2.1.2 bfd_set_error

Synopsis

```
void bfd_set_error (bfd_error_type error_tag);
```

Description

Set the BFD error condition to be *error_tag*.

error_tag must not be bfd_error_on_input. Use bfd_set_input_error for input errors instead.

2.2.1.3 bfd_set_input_error

Synopsis

```
void bfd_set_input_error (bfd *input, bfd_error_type error_tag);
```

Description

Set the BFD error condition to be $bfd_{error_on_input}$. input is the input bfd where the error occurred, and $error_tag$ the bfd_error_type error.

2.2.1.4 bfd_errmsg

Synopsis

```
const char *bfd_errmsg (bfd_error_type error_tag);
```

Description

Return a string describing the error $error_tag$, or the system error if $error_tag$ is bfd_error_system_call.

2.2.1.5 bfd_perror

Synopsis

```
void bfd_perror (const char *message);
```

Description

Print to the standard error stream a string describing the last BFD error that occurred, or the last system error if the last BFD error was a system call failure. If message is non-NULL and non-empty, the error string printed is preceded by message, a colon, and a space. It is followed by a newline.

2.2.2 BFD error handler

Some BFD functions want to print messages describing the problem. They call a BFD error handler function. This function may be overridden by the program.

The BFD error handler acts like vprintf.

```
typedef void (*bfd_error_handler_type) (const_char *, va_list);
```

2.2.2.1 bfd_set_error_handler

Synopsis

```
bfd_error_handler_type bfd_set_error_handler (bfd_error_handler_type);
```

Description

Set the BFD error handler function. Returns the previous function.

2.2.2 bfd_set_error_program_name

Synopsis

```
void bfd_set_error_program_name (const char *);
```

Description

Set the program name to use when printing a BFD error. This is printed before the error message followed by a colon and space. The string must not be changed after it is passed to this function.

2.2.3 BFD assert handler

If BFD nds an internal inconsistency, the bfd assert handler is called with information on the BFD version, BFD source le and line. If this happens, most programs linked against BFD are expected to want to exit with an error, or mark the current BFD operation as failed, so it is recommended to override the default handler, which just calls _bfd_error_handler and continues.

2.2.3.1 bfd_set_assert_handler

Synopsis

```
bfd_assert_handler_type bfd_set_assert_handler (bfd_assert_handler_type);
```

Description

Set the BFD assert handler function. Returns the previous function.

2.3 Miscellaneous

2.3.1 Miscellaneous functions

2.3.1.1 bfd_get_reloc_upper_bound

Synopsis

```
long bfd_get_reloc_upper_bound (bfd *abfd, asection *sect);
```

Description

Return the number of bytes required to store the relocation information associated with section sect attached to bfd abfd. If an error occurs, return -1.

2.3.1.2 bfd_canonicalize_reloc

Synopsis

```
long bfd_canonicalize_reloc
  (bfd *abfd, asection *sec, arelent **loc, asymbol **syms);
```

Description

Call the back end associated with the open BFD abfd and translate the external form of the relocation information attached to sec into the internal canonical form. Place the table into memory at loc, which has been preallocated, usually by a call to $bfd_get_reloc_upper_bound$. Returns the number of relocs, or -1 on error.

The *syms* table is also needed for horrible internal magic reasons.

2.3.1.3 bfd_set_reloc

Synopsis

```
void bfd_set_reloc
  (bfd *abfd, asection *sec, arelent **rel, unsigned int count);
```

Description

Set the relocation pointer and count within section sec to the values rel and count. The argument abfd is ignored.

2.3.1.4 bfd_set_file_flags

Synopsis

```
bfd_boolean bfd_set_file_flags (bfd *abfd, flagword flags);
```

Description

Set the ag word in the BFD abfd to the value flags.

Possible errors are:

- bfd_error_wrong_format The target bfd was not of object format.
- bfd_error_i nvalid_operation The target bfd was open for reading.
- bfd_error_i nvalid_operation The ag word contained a bit which was not applicable to the type of le. E.g., an attempt was made to set the D_PAGED bit on a BFD format which does not support demand paging.

2.3.1.5 bfd_get_arch_size

Synopsis

```
int bfd_get_arch_size (bfd *abfd);
```

Description

Returns the normalized architecture address size, in bits, as determined by the object le's format. By normalized, we mean either 32 or 64. For ELF, this information is included in the header. Use bfd_arch_bits_per_address for number of bits in the architecture address.

Returns

Returns the arch size in bits if known, -1 otherwise.

2.3.1.6 bfd_get_sign_extend_vma

Synopsis

int bfd_get_sign_extend_vma (bfd *abfd);

Description

Indicates if the target architecture "naturally" sign extends an address. Some architectures implicitly sign extend address values when they are converted to types larger than the size of an address. For instance, bfd_get_start_address() will return an address sign extended to II a bfd_vma when this is the case.

Returns

Returns 1 if the target architecture is known to sign extend addresses, 0 if the target architecture is known to not sign extend addresses, and -1 otherwise.

2.3.1.7 bfd_set_start_address

Synopsis

bfd_bool ean bfd_set_start_address (bfd *abfd, bfd_vma vma);

Description

Make *vma* the entry point of output BFD *abfd*.

Returns

Returns TRUE on success, FALSE otherwise.

2.3.1.8 bfd_get_gp_size

Synopsis

unsigned int bfd_get_gp_size (bfd *abfd);

Description

Return the maximum size of objects to be optimized using the GP register under MIPS ECOFF. This is typically set by the -G argument to the compiler, assembler or linker.

2.3.1.9 bfd_set_gp_size

Synopsis

```
void bfd_set_gp_size (bfd *abfd, unsigned int i);
```

Description

Set the maximum size of objects to be optimized using the GP register under ECOFF or MIPS ELF. This is typically set by the -G argument to the compiler, assembler or linker.

2.3.1.10 bfd_scan_vma

Synopsis

bfd_vma bfd_scan_vma (const char *string, const char **end, int base);

Description

Convert, like strtoul, a numerical expression string into a bfd_vma integer, and return that integer. (Though without as many bells and whistles as strtoul.) The expression is assumed to be unsigned (i.e., positive). If given a base, it is used as the base for conversion. A base of 0 causes the function to interpret the string in hex if a leading "0x" or "0X" is found, otherwise in octal if a leading zero is found, otherwise in decimal.

If the value would over ow, the maximum bfd_vma value is returned.

2.3.1.11 bfd_copy_private_header_data

Synopsis

bfd_boolean bfd_copy_private_header_data (bfd *ibfd, bfd *obfd);

Description

Copy private BFD header information from the BFD *ibfd* to the BFD *obfd*. This copies information that may require sections to exist, but does not require symbol tables. Return true on success, fal se on error. Possible error returns are:

2.3.1.12 bfd_copy_private_bfd_data

Synopsis

bfd_boolean bfd_copy_private_bfd_data (bfd *ibfd, bfd *obfd);

Description

Copy private BFD information from the BFD *ibfd* to the the BFD *obfd*. Return TRUE on success, FALSE on error. Possible error returns are:

2.3.1.13 bfd_set_private_flags

Synopsis

bfd_boolean bfd_set_private_flags (bfd *abfd, flagword flags);

Description

Set private BFD ag information in the BFD *abfd*. Return TRUE on success, FALSE on error. Possible error returns are:

2.3.1.14 Other functions

Description

The following functions exist but have not yet been documented.

```
#define bfd_sizeof_headers(abfd, info) \
    BFD_SEND (abfd, _bfd_sizeof_headers, (abfd, info))
```

```
#define bfd_find_nearest_line_discriminator(abfd, sec, syms, off, file, func, \■

  (bfd *, struct bfd_link_info *, struct bfd_link_order *, bfd_byte *,
  bfd_boolean, asymbol **);
```

2.3.1.15 bfd_alt_mach_code

Synopsis

bfd boolean bfd alt mach code (bfd *abfd, int alternative);

Description

When more than one machine code number is available for the same machine type, this

function can be used to switch between the preferred one (alternative == 0) and any others. Currently, only ELF supports this feature, with up to two alternate machine codes.

2.3.1.16 bfd_emul_get_maxpagesize

Synopsis

```
bfd_vma bfd_emul_get_maxpagesize (const char *);
```

Description

Returns the maximum page size, in bytes, as determined by emulation.

Returns

Returns the maximum page size in bytes for ELF, 0 otherwise.

2.3.1.17 bfd_emul_set_maxpagesize

Synopsis

```
void bfd_emul_set_maxpagesize (const char *, bfd_vma);
```

Description

For ELF, set the maximum page size for the emulation. It is a no-op for other formats.

2.3.1.18 bfd_emul_get_commonpagesize

Synopsis

```
bfd_vma bfd_emul_get_commonpagesize (const char *);
```

Description

Returns the common page size, in bytes, as determined by emulation.

Returns

Returns the common page size in bytes for ELF, 0 otherwise.

2.3.1.19 bfd_emul_set_commonpagesize

Synopsis

```
void bfd emul set commonpagesize (const char *, bfd vma);
```

Description

For ELF, set the common page size for the emulation. It is a no-op for other formats.

2.3.1.20 bfd_demangle

Synopsis

```
char *bfd_demangle (bfd *, const char *, int);
```

Description

Wrapper around cplus_demangle. Strips leading underscores and other such chars that would otherwise confuse the demangler. If passed a g++ v3 ABI mangled name, returns a bu er allocated with malloc holding the demangled name. Returns NULL otherwise and on memory alloc failure.

2.3.1.21 bfd_update_compression_header

Synopsis

```
void bfd_update_compression_header
  (bfd *abfd, bfd_byte *contents, asection *sec);
```

Description

Set the compression header at CONTENTS of SEC in ABFD and update elf_section_ ags for compression.

2.3.1.22 bfd_check_compression_header

Synopsis

```
bfd_boolean bfd_check_compression_header
  (bfd *abfd, bfd_byte *contents, asection *sec,
    bfd_size_type *uncompressed_size);
```

Description

Check the compression header at CONTENTS of SEC in ABFD and store the uncompressed size in UNCOMPRESSED_SIZE if the compression header is valid.

Returns

Return TRUE if the compression header is valid.

2.3.1.23 bfd_get_compression_header_size

Synopsis

```
int bfd_get_compression_header_size (bfd *abfd, asection *sec);
```

Description

Return the size of the compression header of SEC in ABFD.

Returns

Return the size of the compression header in bytes.

2.3.1.24 bfd_convert_section_size

Synopsis

```
bfd_size_type bfd_convert_section_size
  (bfd *ibfd, asection *isec, bfd *obfd, bfd_size_type size);
```

Description

Convert the size *size* of the section *isec* in input BFD *ibfd* to the section size in output BFD *obfd*.

2.3.1.25 bfd_convert_section_contents

Synopsis

```
bfd_boolean bfd_convert_section_contents
  (bfd *ibfd, asection *isec, bfd *obfd,
   bfd byte **ptr, bfd size type *ptr size);
```

Description

Convert the contents, stored in *ptr, of the section isec in input BFD ibfd to output BFD obfd if needed. The original bu er pointed to by *ptr may be freed and *ptr is returned with memory malloc'd by this function, and the new size written to ptr_size.

2.3.1.26 struct bfd_iovec

Description

The struct bfd_i ovec contains the internal le I/O class. Each BFD has an instance of this class and all le I/O is routed through it (it is assumed that the instance implements all methods listed below).

```
struct bfd iovec
 /* To avoid problems with macros, a "b" rather than "f"
     prefix is prepended to each method name.
 /* Attempt to read/write NBYTES on ABFD's IOSTREAM storing/fetching
     bytes starting at PTR. Return the number of bytes actually
     transfered (a read past end-of-file returns less than NBYTES),
     or -1 (setting bfd_error) if an error occurs. */
 file ptr (*bread) (struct bfd *abfd, void *ptr, file ptr nbytes);
 file_ptr (*bwrite) (struct bfd *abfd, const void *ptr,
                     file_ptr nbytes);
 /* Return the current IOSTREAM file offset, or -1 (setting bfd_error
     if an error occurs. */
 file ptr (*btell) (struct bfd *abfd);
  /* For the following, on successful completion a value of 0 is returned.■
     Otherwise, a value of -1 is returned (and bfd_error is set).
 int (*bseek) (struct bfd *abfd, file ptr offset, int whence);
 int (*bclose) (struct bfd *abfd);
 int (*bflush) (struct bfd *abfd);
 int (*bstat) (struct bfd *abfd, struct stat *sb);
  /* Mmap a part of the files. ADDR, LEN, PROT, FLAGS and OFFSET are the usual ■
    mmap parameter, except that LEN and OFFSET do not need to be page
              Returns (void *)-1 on failure, mmapped address on success. ■
     Also write in MAP ADDR the address of the page aligned buffer and in
     MAP_LEN the size mapped (a page multiple). Use unmap with MAP_ADDR and
    MAP LEN to unmap.
 void *(*bmmap) (struct bfd *abfd, void *addr, bfd_size_type len,
                 int prot, int flags, file_ptr offset,
                 void **map_addr, bfd_size_type *map_len);
};
extern const struct bfd_i ovec _bfd_memory_i ovec;
```

2.3.1.27 bfd_get_mtime

Synopsis

long bfd_get_mtime (bfd *abfd);

Description

Return the le modi cation time (as read from the le system, or from the archive header for archive members).

2.3.1.28 bfd_get_size

Synopsis

```
ufile_ptr bfd_get_size (bfd *abfd);
```

Description

Return the le size (as read from le system) for the le associated with BFD abfd.

The initial motivation for, and use of, this routine is not so we can get the exact size of the object the BFD applies to, since that might not be generally possible (archive members for example). It would be ideal if someone could eventually modify it so that such results were guaranteed.

Instead, we want to ask questions like "is this NNN byte sized object I'm about to try read from le o set YYY reasonable?" As as example of where we might do this, some object formats use string tables for which the rst sizeof (I ong) bytes of the table contain the size of the table itself, including the size bytes. If an application tries to read what it thinks is one of these string tables, without some way to validate the size, and for some reason the size is wrong (byte swapping error, wrong location for the string table, etc.), the only clue is likely to be a read error when it tries to read the table, or a "virtual memory exhausted" error when it tries to allocate 15 bazillon bytes of space for the 15 bazillon byte table it is about to read. This function at least allows us to answer the question, "is the size reasonable?".

2.3.1.29 bfd_get_file_size

Synopsis

```
ufile_ptr bfd_get_file_size (bfd *abfd);
```

Description

Return the le size (as read from le system) for the le associated with BFD *abfd*. It supports both normal les and archive elements.

2.3.1.30 bfd_mmap

Synopsis

```
void *bfd_mmap (bfd *abfd, void *addr, bfd_size_type len,
   int prot, int flags, file_ptr offset,
   void **map_addr, bfd_size_type *map_len);
```

Description

Return mmap()ed region of the le, if possible and implemented. LEN and OFFSET do not need to be page aligned. The page aligned address and length are written to MAP_ADDR and MAP_LEN.

2.4 Memory Usage

BFD keeps all of its internal structures in obstacks. There is one obstack per open BFD le, into which the current state is stored. When a BFD is closed, the obstack is deleted, and so everything which has been allocated by BFD for the closing le is thrown away.

BFD does not free anything created by an application, but pointers into bfd structures become invalid on a bfd_cl ose; for example, after a bfd_cl ose the vector passed to bfd_canonicalize_symtab is still around, since it has been allocated by the application, but the data that it pointed to are lost.

The general rule is to not close a BFD until all operations dependent upon data from the BFD have been completed, or all the data from within the le has been copied. To help with the management of memory, there is a function (bfd_alloc_size) which returns the number of bytes in obstacks associated with the supplied BFD. This could be used to select the greediest open BFD, close it to reclaim the memory, perform some operation and reopen the BFD again, to get a fresh copy of the data structures.

2.5 Initialization

2.5.1 Initialization functions

These are the functions that handle initializing a BFD.

2.5.1.1 bfd_init

Synopsis

void bfd_init (void);

Description

This routine must be called before any other BFD function to initialize magical internal data structures.

2.6 Sections

The raw data contained within a BFD is maintained through the section abstraction. A single BFD may have any number of sections. It keeps hold of them by pointing to the rst; each one points to the next in the list.

Sections are supported in BFD in section. c.

2.6.1 Section input

When a BFD is opened for reading, the section structures are created and attached to the BFD.

Each section has a name which describes the section in the outside world | for example, a. out would contain at least three sections, called . text, . data and . bss.

Names need not be unique; for example a COFF le may have several sections named . data.

Sometimes a BFD will contain more than the \natural" number of sections. A back end may attach other sections containing constructor data, or an application may add a section (using bfd_make_section) to the sections attached to an already open BFD. For example, the linker creates an extra section COMMON for each input le's BFD to hold information about common storage.

The raw data is not necessarily read in when the section descriptor is created. Some targets may leave the data in place until a bfd_get_section_contents call is made. Other back ends may read in all the data at once. For example, an S-record le has to be read once to determine the size of the data. An IEEE-695 le doesn't contain raw data in sections, but data and relocation expressions intermixed, so the data area has to be parsed to get out the data and relocations.

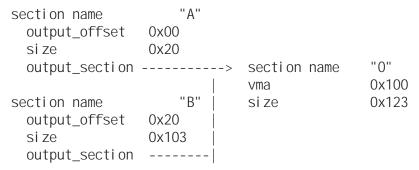

2.6.2 Section output

To write a new object style BFD, the various sections to be written have to be created. They are attached to the BFD in the same way as input sections; data is written to the sections using bfd_set_section_contents.

Any program that creates or combines sections (e.g., the assembler and linker) must use the assection elds output_section and output_offset to indicate the le sections to which each section must be written. (If the section is being created from scratch, output_section should probably point to the section itself and output_offset should probably be zero.)

The data to be written comes from input sections attached (via output_section pointers) to the output sections. The output section structure can be considered a liter for the input section: the output section determines the vma of the output data and the name, but the input section determines the o set into the output section of the data to be written.

E.g., to create a section "O", starting at 0x100, 0x123 long, containing two subsections, "A" at o set 0x0 (i.e., at vma 0x100) and "B" at o set 0x20 (i.e., at vma 0x120) the asection structures would look like:

2.6.3 Link orders

The data within a section is stored in a $link_order$. These are much like the xups in gas. The link_order abstraction allows a section to grow and shrink within itself.

A link_order knows how big it is, and which is the next link_order and where the raw data for it is; it also points to a list of relocations which apply to it.

The link_order is used by the linker to perform relaxing on nal code. The compiler creates code which is as big as necessary to make it work without relaxing, and the user can select whether to relax. Sometimes relaxing takes a lot of time. The linker runs around the relocations to see if any are attached to data which can be shrunk, if so it does it on a link_order by link_order basis.

2.6.4 typedef asection

Here is the section structure:

```
typedef struct bfd_section
{
   /* The name of the section; the name isn't a copy, the pointer is
      the same as that passed to bfd_make_section. */
   const char *name;
```

```
/* A unique sequence number. */
 unsigned int id:
  /* Which section in the bfd; 0..n-1 as sections are created in a bfd. */
 unsigned intindex:
  /* The next section in the list belonging to the BFD, or NULL. */
 struct bfd section *next;
  /* The previous section in the list belonging to the BFD, or NULL. */
  struct bfd_section *prev;
 /* The field flags contains attributes of the section. Some
     flags are read in from the object file, and some are
     synthesized from other information. */
  flagword flags;
#define SEC_NO_FLAGS
                                          0x0
  /* Tells the OS to allocate space for this section when loading.
     This is clear for a section containing debug information only. */
#define SEC_ALLOC
                                          0x1

```

2.6.5 Section prototypes

These are the functions exported by the section handling part of BFD.

2.6.5.1 bfd_section_list_clear

Synopsis

```
void bfd_section_list_clear (bfd *);
```

Description

Clears the section list, and also resets the section count and hash table entries.

2.6.5.2 bfd_get_section_by_name

asection *bfd_get_section_by_name (bfd *abfd, const char *name);

Description

Return the most recently created section attached to *abfd* named *name*. Return NULL if no such section exists.

2.6.5.3 bfd_get_next_section_by_name

Synopsis

```
asection *bfd_get_next_section_by_name (bfd *ibfd, asection *sec);
```

Description

Given sec is a section returned by bfd_get_section_by_name, return the next most recently created section attached to the same BFD with the same name, or if no such section exists in the same BFD and IBFD is non-NULL, the next section with the same name in any input BFD following IBFD. Return NULL on nding no section.

2.6.5.4 bfd_get_linker_section

Synopsis

```
asection *bfd_get_linker_section (bfd *abfd, const char *name);
```

Description

Return the linker created section attached to *abfd* named *name*. Return NULL if no such section exists.

2.6.5.5 bfd_get_section_by_name_if

Synopsis

```
asection *bfd_get_section_by_name_if
  (bfd *abfd,
    const char *name,
    bfd_boolean (*func) (bfd *abfd, asection *sect, void *obj),
    void *obj);
```

Description

Call the provided function func for each section attached to the BFD abfd whose name matches name, passing obj as an argument. The function will be called as if by

```
func (abfd, the_section, obj);
```

It returns the rst section for which func returns true, otherwise NULL.

2.6.5.6 bfd_get_unique_section_name

Synopsis

```
char *bfd_get_unique_section_name
  (bfd *abfd, const char *templat, int *count);
```

Description

Invent a section name that is unique in *abfd* by tacking a dot and a digit su x onto the original *templat*. If *count* is non-NULL, then it speci es the rst number tried as a su x to generate a unique name. The value pointed to by *count* will be incremented in this case.

2.6.5.7 bfd_make_section_old_way

Synopsis

```
asection *bfd_make_section_old_way (bfd *abfd, const char *name);
```

Description

Create a new empty section called *name* and attach it to the end of the chain of sections for the BFD *abfd*. An attempt to create a section with a name which is already in use returns its pointer without changing the section chain.

It has the funny name since this is the way it used to be before it was rewritten....

Possible errors are:

- bfd_error_i nvalid_operation If output has already started for this BFD.
- bfd_error_no_memory If memory allocation fails.

2.6.5.8 bfd_make_section_anyway_with_flags

Synopsis

```
asection *bfd_make_section_anyway_with_flags
  (bfd *abfd, const char *name, flagword flags);
```

Description

Create a new empty section called name and attach it to the end of the chain of sections for abfd. Create a new section even if there is already a section with that name. Also set the attributes of the new section to the value flagts.

Return NULL and set bfd_error on error; possible errors are:

- bfd_error_invalid_operation If output has already started for abfd.
- bfd_error_no_memory If memory allocation fails.

2.6.5.9 bfd_make_section_anyway

Synopsis

```
asection *bfd_make_section_anyway (bfd *abfd, const char *name);
```

Description

Create a new empty section called name and attach it to the end of the chain of sections for abfd. Create a new section even if there is already a section with that name.

Return NULL and set bfd_error on error; possible errors are:

- bfd_error_i nval i d_operati on If output has already started for abfd.
- bfd_error_no_memory If memory allocation fails.

2.6.5.10 bfd_make_section_with_flags

Synopsis

```
asection *bfd_make_section_with_flags
  (bfd *, const char *name, flagword flags);
```

Description

Like bfd_make_secti on_anyway, but return NULL (without calling bfd_set_error ()) without changing the section chain if there is already a section named *name*. Also set the attributes of the new section to the value *flags*. If there is an error, return NULL and set bfd_error.

2.6.5.11 bfd_make_section

Synopsis

```
asection *bfd_make_section (bfd *, const char *name);
```

Description

Like bfd_make_section_anyway, but return NULL (without calling bfd_set_error ()) without changing the section chain if there is already a section named name. If there is an error, return NULL and set bfd_error.

2.6.5.12 bfd_get_next_section_id

Synopsis

```
int bfd get next section id (void);
```

Description

Returns the id that the next section created will have.

2.6.5.13 bfd_set_section_flags

Synopsis

```
bfd_boolean bfd_set_section_flags
  (bfd *abfd, asection *sec, flagword flags);
```

Description

Set the attributes of the section sec in the BFD abfd to the value flags. Return TRUE on success, FALSE on error. Possible error returns are:

• bfd_error_invalid_operation - The section cannot have one or more of the attributes requested. For example, a .bss section in a. out may not have the SEC_HAS_ CONTENTS eld set.

2.6.5.14 bfd_rename_section

Synopsis

```
void bfd_rename_section
  (bfd *abfd, asection *sec, const char *newname);
```

Description

Rename section sec in abfd to newname.

2.6.5.15 bfd_map_over_sections

Synopsis

```
void bfd_map_over_sections
  (bfd *abfd,
    void (*func) (bfd *abfd, asection *sect, void *obj),
    void *obj);
```

Description

Call the provided function func for each section attached to the BFD abfd, passing obj as an argument. The function will be called as if by

```
func (abfd, the_section, obj);
```

This is the preferred method for iterating over sections; an alternative would be to use a loop:

```
asection *p;
for (p = abfd->sections; p != NULL; p = p->next)
  func (abfd, p, ...)
```

2.6.5.16 bfd_sections_find_if

Synopsis

```
asection *bfd_sections_find_if
  (bfd *abfd,
    bfd_boolean (*operation) (bfd *abfd, asection *sect, void *obj),
    void *obj);
```

Description

Call the provided function operation for each section attached to the BFD abfd, passing obj as an argument. The function will be called as if by

```
operation (abfd, the_section, obj);
```

It returns the rst section for which operation returns true.

2.6.5.17 bfd_set_section_size

Synopsis

```
bfd_boolean bfd_set_section_size
   (bfd *abfd, asection *sec, bfd_size_type val);
```

Description

Set sec to the size val. If the operation is ok, then TRUE is returned, else FALSE.

Possible error returns:

• bfd_error_i nval i d_operati on - Writing has started to the BFD, so setting the size is invalid.

2.6.5.18 bfd_set_section_contents

Synopsis

```
bfd_boolean bfd_set_section_contents
  (bfd *abfd, asection *section, const void *data,
    file_ptr offset, bfd_size_type count);
```

Description

Sets the contents of the section section in BFD abfd to the data starting in memory at data. The data is written to the output section starting at o set offset for count octets.

Normally TRUE is returned, else FALSE. Possible error returns are:

- bfd_error_no_contents The output section does not have the SEC_HAS_CONTENTS attribute, so nothing can be written to it.
- and some more too

This routine is front end to the back end function _bfd_set_section_contents.

2.6.5.19 bfd_get_section_contents

Synopsis

```
bfd_boolean bfd_get_section_contents
  (bfd *abfd, asection *section, void *location, file_ptr offset,
    bfd_size_type count);
```

Description

Read data from section in BFD abfd into memory starting at location. The data is read at an o set of offset from the start of the input section, and is read for count bytes.

If the contents of a constructor with the SEC_CONSTRUCTOR ag set are requested or if the section does not have the SEC_HAS_CONTENTS ag set, then the *location* is Iled with zeroes. If no errors occur, TRUE is returned, else FALSE.

2.6.5.20 bfd_malloc_and_get_section

Synopsis

```
bfd_boolean bfd_malloc_and_get_section
  (bfd *abfd, asection *section, bfd_byte **buf);
```

Description

Read all data from section in BFD abfd into a bu er, *buf, malloc'd by this function.

2.6.5.21 bfd_copy_private_section_data

Synopsis

```
bfd_boolean bfd_copy_private_section_data
   (bfd *ibfd, asection *isec, bfd *obfd, asection *osec);
```

Description

Copy private section information from *isec* in the BFD *ibfd* to the section *osec* in the BFD *obfd*. Return TRUE on success, FALSE on error. Possible error returns are:

2.6.5.22 bfd_generic_is_group_section

Synopsis

```
bfd_boolean bfd_generic_is_group_section (bfd *, const asection *sec);
```

Description

Returns TRUE if sec is a member of a group.

2.6.5.23 bfd_generic_discard_group

Synopsis

```
bfd boolean bfd generic discard group (bfd *abfd, asection *group);
```

Description

Remove all members of group from the output.

2.7 Symbols

BFD tries to maintain as much symbol information as it can when it moves information from le to le. BFD passes information to applications though the asymbol structure. When the application requests the symbol table, BFD reads the table in the native form and translates parts of it into the internal format. To maintain more than the information passed to applications, some targets keep some information \behind the scenes" in a structure only the particular back end knows about. For example, the co back end keeps the original symbol table structure as well as the canonical structure when a BFD is read in. On output, the co back end can reconstruct the output symbol table so that no information is lost, even information unique to co which BFD doesn't know or understand. If a co symbol table were read, but were written through an a.out back end, all the co speci c information would be lost. The symbol table of a BFD is not necessarily read in until a canonicalize request is made. Then the BFD back end Ils in a table provided by the application with pointers to the canonical information. To output symbols, the application provides BFD with a table of pointers to pointers to asymbols. This allows applications like the linker to output a symbol as it was read, since the \behind the scenes" information will be still available.

2.7.1 Reading symbols

There are two stages to reading a symbol table from a BFD: allocating storage, and the actual reading process. This is an excerpt from an application which reads the symbol table:

```
long storage_needed;
asymbol **symbol_table;
long number of symbols;
Iong i;
storage_needed = bfd_get_symtab_upper_bound (abfd);
if (storage_needed < 0)</pre>
 FAIL
if (storage_needed == 0)
  return:
symbol_table = xmalloc (storage needed);
number of symbols =
   bfd_canonicalize_symtab (abfd, symbol_table);
if (number_of_symbols < 0)</pre>
  FAIL
for (i = 0; i < number of symbols; i++)
  process_symbol (symbol_table[i]);
```

All storage for the symbols themselves is in an objalloc connected to the BFD; it is freed when the BFD is closed.

2.7.2 Writing symbols

Writing of a symbol table is automatic when a BFD open for writing is closed. The application attaches a vector of pointers to pointers to symbols to the BFD being written, and Ils in the symbol count. The close and cleanup code reads through the table provided and performs all the necessary operations. The BFD output code must always be provided with an \owned" symbol: one which has come from another BFD, or one which has been created using bfd_make_empty_symbol. Here is an example showing the creation of a symbol table with only one element:

```
#include "sysdep.h"
#include "bfd.h"
int main (void)
{
  bfd *abfd:
  asymbol *ptrs[2];
  asymbol *new;
  abfd = bfd_openw ("foo", "a. out-sunos-big");
  bfd_set_format (abfd, bfd_object);
  new = bfd_make_empty_symbol (abfd);
  new->name = "dummy_symbol";
  new->section = bfd make section old way (abfd, ".text");
  new->flags = BSF_GLOBAL;
  new->value = 0x12345:
  ptrs[0] = new;
  ptrs[1] = 0;
  bfd_set_symtab (abfd, ptrs, 1);
  bfd_close (abfd);
  return 0;
}
./makesym
nm foo
00012345 A dummy_symbol
```

Many formats cannot represent arbitrary symbol information; for instance, the a. out object format does not (ini 0 as)-301not atraes m48(sym)28(banothes)-301hessymb poinw2of whic

of each symbol. The pointer is allocated using malloc, and should be freed by the caller when it is no longer needed.

The function bfd_mi ni symbol _to_symbol will take a pointer to a minisymbol, and a pointer to a structure returned by bfd_make_empty_symbol, and return a asymbol structure. The return value may or may not be the same as the value from bfd_make_empty_symbol which was passed in.

2.7.4 typedef asymbol

An asymbol has the form:

```
typedef struct bfd_symbol
 /* A pointer to the BFD which owns the symbol. This information
    is necessary so that a back end can work out what additional
    information (invisible to the application writer) is carried
    with the symbol.
    This field is *almost* redundant, since you can use section->owner
    instead, except that some symbols point to the global sections
    bfd_{abs,com,und}_section. This could be fixed by making
    these globals be per-bfd (or per-target-flavor). FIXME.
 struct bfd *the_bfd; /* Use bfd_asymbol_bfd(sym) to access this field. */
  /* The text of the symbol. The name is left alone, and not copied; the
    application may not alter it. */
 const char *name;
 /* The value of the symbol. This really should be a union of a
    numeric value with a pointer, since some flags indicate that
    a pointer to another symbol is stored here. */

}
asymbol;
```

2.7.5 Symbol handling functions

2.7.5.1 bfd_get_symtab_upper_bound

Description

Return the number of bytes required to store a vector of pointers to asymbols for all the symbols in the BFD abfd, including a terminal NULL pointer. If there are no symbols in the BFD, then return 0. If an error occurs, return -1.

```
#defi ne bfd_get_symtab_upper_bound(abfd) \
    BFD_SEND (abfd, _bfd_get_symtab_upper_bound, (abfd))
```

2.7.5.2 bfd_is_local_label

Synopsis

```
bfd_boolean bfd_is_local_label (bfd *abfd, asymbol *sym);
```

Description

Return TRUE if the given symbol sym in the BFD abfd is a compiler generated local label, else return FALSE.

2.7.5.3 bfd_is_local_label_name

Synopsis

```
bfd boolean bfd is local label name (bfd *abfd, const char *name);
```

Description

Return TRUE if a symbol with the name name in the BFD abfd is a compiler generated local label, else return FALSE. This just checks whether the name has the form of a local label.

```
#define bfd_is_local_label_name(abfd, name) \
    BFD_SEND (abfd, _bfd_is_local_label_name, (abfd, name))
```

2.7.5.4 bfd_is_target_special_symbol

bfd_boolean bfd_is_target_special_symbol (bfd *abfd, asymbol *sym);

Description

Return TRUE i a symbol sym in the BFD abfd is something special to the particular target represented by the BFD. Such symbols should normally not be mentioned to the user.

```
#define bfd_is_target_special_symbol (abfd, sym) \
    BFD_SEND (abfd, _bfd_is_target_special_symbol, (abfd, sym))
```

2.7.5.5 bfd_canonicalize_symtab

Description

Read the symbols from the BFD abfd, and IIs in the vector location with pointers to the symbols and a trailing NULL. Return the actual number of symbol pointers, not including the NULL.

```
#define bfd_canonicalize_symtab(abfd, location) \
    BFD_SEND (abfd, _bfd_canonicalize_symtab, (abfd, location))
```

2.7.5.6 bfd_set_symtab

Synopsis

```
bfd_boolean bfd_set_symtab
   (bfd *abfd, asymbol **location, unsigned int count);
```

Description

Arrange that when the output BFD *abfd* is closed, the table *location* of *count* pointers to symbols will be written.

2.7.5.7 bfd_print_symbol_vandf

Synopsis

```
void bfd print symbol vandf (bfd *abfd, void *file, asymbol *symbol);
```

Description

Print the value and ags of the *symbol* supplied to the stream *file*.

2.7.5.8 bfd_make_empty_symbol

Description

Create a new asymbol structure for the BFD abfd and return a pointer to it.

This routine is necessary because each back end has private information surrounding the asymbol. Building your own asymbol and pointing to it will not create the private information, and will cause problems later on.

```
#define bfd_make_empty_symbol (abfd) \
    BFD_SEND (abfd, _bfd_make_empty_symbol, (abfd))
```

2.7.5.9 _bfd_generic_make_empty_symbol

```
asymbol *_bfd_generic_make_empty_symbol (bfd *);
```

Create a new asymbol structure for the BFD abfd and return a pointer to it. Used by core le routines, binary back-end and anywhere else where no private info is needed.

2.7.5.10 bfd_make_debug_symbol

Description

Create a new asymbol structure for the BFD abfd, to be used as a debugging symbol. Further details of its use have yet to be worked out.

```
#define bfd_make_debug_symbol (abfd, ptr, size) \
    BFD_SEND (abfd, _bfd_make_debug_symbol, (abfd, ptr, size))
```

2.7.5.11 bfd_decode_symclass

Description

Return a character corresponding to the symbol class of symbol, or '?' for an unknown class.

Synopsis

```
int bfd_decode_symclass (asymbol *symbol);
```

2.7.5.12 bfd_is_undefined_symclass

Description

Returns non-zero if the class symbol returned by bfd_decode_symclass represents an undened symbol. Returns zero otherwise.

Synopsis

```
bfd_boolean bfd_is_undefined_symclass (int symclass);
```

2.7.5.13 bfd_symbol_info

Description

Fill in the basic info about symbol that nm needs. Additional info may be added by the back-ends after calling this function.

Synopsis

```
void bfd_symbol_info (asymbol *symbol, symbol_info *ret);
```

2.7.5.14 bfd_copy_private_symbol_data

Synopsis

```
bfd_boolean bfd_copy_private_symbol_data
  (bfd *ibfd, asymbol *isym, bfd *obfd, asymbol *osym);
```

Description

Copy private symbol information from isym in the BFD ibfd to the symbol osym in the BFD obfd. Return TRUE on success, FALSE on error. Possible error returns are:

• bfd_error_no_memory - Not enough memory exists to create private data for osec.

2.8 Archives

Description

An archive (or library) is just another BFD. It has a symbol table, although there's not much a user program will do with it.

The big difference between an archive BFD and an ordinary BFD is that the archive doesn't have sections. Instead it has a chain of BFDs that are considered its contents. These BFDs can be manipulated like any other. The BFDs contained in an archive opened for reading will all be opened for reading. You may put either input or output BFDs into an archive opened for output; they will be handled correctly when the archive is closed.

Use bfd_openr_next_archi ved_file to step through the contents of an archive opened for input. You don't have to read the entire archive if you don't want to! Read it until you not what you want.

A BFD returned by bfd_openr_next_archi ved_file can be closed manually with bfd_close. If you do not close it, then a second iteration through the members of an archive may return the same BFD. If you close the archive BFD, then all the member BFDs will automatically be closed as well.

Archive contents of output BFDs are chained through the archive_next pointer in a BFD. The rst one is ndable through the archive_head slot of the archive. Set it with bfd_set_archive_head (q.v.). A given BFD may be in only one open output archive at a time.

As expected, the BFD archive code is more general than the archive code of any given environment. BFD archives may contain les of di erent formats (e.g., a.out and co) and even di erent architectures. You may even place archives recursively into archives!

This can cause unexpected confusion, since some archive formats are more expressive than others. For instance, Intel COFF archives can preserve long lenames; SunOS a.out archives cannot. If you move a le from the rst to the second format and back again, the lename may be truncated. Likewise, di erent a.out environments have di erent conventions as to how they truncate lenames, whether they preserve directory names in lenames, etc. When interoperating with native tools, be sure your les are homogeneous.

Beware: most of these formats do not react well to the presence of spaces in lenames. We do the best we can, but can't always handle this case due to restrictions in the format of archives. Many Unix utilities are braindead in regards to spaces and such in lenames anyway, so this shouldn't be much of a restriction.

Archives are supported in BFD in archive. c.

2.8.1 Archive functions

2.8.1.1 bfd_get_next_mapent

```
symindex bfd_get_next_mapent
  (bfd *abfd, symindex previous, carsym **sym);
```

Step through archive abfd's symbol table (if it has one). Successively update sym with the next symbol's information, returning that symbol's (internal) index into the symbol table.

Supply BFD_NO_MORE_SYMBOLS as the *previous* entry to get the rst one; returns BFD_NO_MORE_SYMBOLS when you've already got the last one.

A carsym is a canonical archive symbol. The only user-visible element is its name, a null-terminated string.

2.8.1.2 bfd_set_archive_head

Synopsis

```
bfd_bool ean bfd_set_archi ve_head (bfd *output, bfd *new_head);
```

Description

Set the head of the chain of BFDs contained in the archive *output* to *new_head*.

2.8.1.3 bfd_openr_next_archived_file

Synopsis

```
bfd *bfd openr_next_archived_file (bfd *archive, bfd *previous);
```

Description

Provided a BFD, *archive*, containing an archive and NULL, open an input BFD on the rst contained element and returns that. Subsequent calls should pass the archive and the previous return value to return a created BFD to the next contained element. NULL is returned when there are no more. Note - if you want to process the bfd returned by this call be sure to call bfd_check_format() on it rst.

2.9 File formats

A format is a BFD concept of high level le contents type. The formats supported by BFD are:

• bfd_object

The BFD may contain data, symbols, relocations and debug info.

bfd_archi ve

The BFD contains other BFDs and an optional index.

• bfd core

The BFD contains the result of an executable core dump.

2.9.1 File format functions

2.9.1.1 bfd_check_format

```
bfd_boolean bfd_check_format (bfd *abfd, bfd_format format);
```

Verify if the le attached to the BFD *abfd* is compatible with the format *format* (i.e., one of bfd_obj ect, bfd_archi ve or bfd_core).

If the BFD has been set to a speci c target before the call, only the named target and format combination is checked. If the target has not been set, or has been set to default, then all the known target backends is interrogated to determine a match. If the default target matches, it is used. If not, exactly one target must recognize the le, or an error results.

The function returns TRUE on success, otherwise FALSE with one of the following error codes:

- bfd_error_invalid_operation if format is not one of bfd_object, bfd_archive or bfd_core.
- bfd_error_system_call if an error occured during a read even some le mismatches can cause bfd_error_system_calls.
- file_not_recognised none of the backends recognised the le format.
- bfd_error_file_ambi guously_recognized more than one backend recognised the le format.

2.9.1.2 bfd_check_format_matches

Synopsis

```
bfd_boolean bfd_check_format_matches
  (bfd *abfd, bfd_format format, char ***matching);
```

Description

Like bfd_check_format, except when it returns FALSE with bfd_errno set to bfd_error_file_ambi guously_recognized. In that case, if matching is not NULL, it will be lied in with a NULL-terminated list of the names of the formats that matched, allocated with malloc. Then the user may choose a format and try again.

When done with the list that matching points to, the caller should free it.

2.9.1.3 bfd_set_format

Synopsis

```
bfd_boolean bfd_set_format (bfd *abfd, bfd_format format);
```

Description

This function sets the le format of the BFD *abfd* to the format *format*. If the target set in the BFD does not support the format requested, the format is invalid, or the BFD is not open for writing, then an error occurs.

2.9.1.4 bfd_format_string

Synopsis

```
const char *bfd_format_string (bfd_format format);
```

Description

Return a pointer to a const string invalid, object, archive, core, or unknown, depending upon the value of *format*.

2.10 Relocations

BFD maintains relocations in much the same way it maintains symbols: they are left alone until required, then read in en-masse and translated into an internal form. A common routine bfd_perform_rel ocation acts upon the canonical form to do the xup.

Relocations are maintained on a per section basis, while symbols are maintained on a per BFD basis.

All that a back end has to do to the BFD interface is to create a struct reloc_cache_entry for each relocation in a particular section, and II in the right bits of the structures.

2.10.1 typedef arelent

This is the structure of a relocation entry:

```
typedef enum bfd_reloc_status
  /* No errors detected. Note - the value 2 is used so that it
    will not be mistaken for the boolean TRUE or FALSE values.
 bfd reloc ok = 2,
 /* The relocation was performed, but there was an overflow. */
 bfd reloc overflow,
 /* The address to relocate was not within the section supplied.
 bfd_rel oc_outofrange,
 /* Used by special functions. */
 bfd_reloc_continue,
 /* Unsupported relocation size requested. */
 bfd reloc notsupported,
 /* Unused. */
 bfd_reloc_other,
 /* The symbol to relocate against was undefined. */
 bfd reloc undefined,
 /* The relocation was performed, but may not be ok - presently
     generated only when linking i960 coff files with i960 b.out
     symbols. If this type is returned, the error message argument
     to bfd perform relocation will be set. */
 bfd_reloc_dangerous
 bfd_reloc_status_type;
typedef struct reloc_cache_entry
```

```
{
    /* A pointer into the canonical table of pointers. */
    struct bfd_symbol **sym_ptr_ptr;

    /* offset in section. */
    bfd_size_type address;

    /* addend for relocation value. */
    bfd_vma addend;

    /* Pointer to how to perform the required relocation. */
    reloc_howto_type *howto;
}
arelent;
```

Here is a description of each of the elds within an arel ent:

• sym_ptr_ptr

The symbol table pointer points to a pointer to the symbol associated with the relocation request. It is the pointer into the table returned by the back end's canoni cal i ze_symtab action. See Section 2.7 [Symbols], page 44. The symbol is referenced through a pointer to a pointer so that tools like the linker can x up all the symbols of the same name by modifying only one pointer. The relocation routine looks in the symbol and uses the base of the section the symbol is attached to and the value of the symbol as the initial relocation o set. If the symbol pointer is zero, then the section provided is looked up.

address

The address eld gives the o set in bytes from the base of the section data which owns the relocation record to the rst byte of relocatable information. The actual data relocated will be relative to this point; for example, a relocation type which modi es the bottom two bytes of a four byte word would not touch the rst byte pointed to in a big endian world.

addend

The addend is a value provided by the back end to be added (!) to the relocation o set. Its interpretation is dependent upon the howto. For example, on the 68k the code:

```
char foo[];
main()

{
return foo[0x12345678];
}
Could be compiled into:

linkw fp, #-4
moveb @#12345678, d0
extbl d0
unlk fp
```

rts

This could create a reloc pointing to foo, but leave the o set in the data, something like:

```
RELOCATION RECORDS FOR [.text]:
offset
        type
                  value
00000006 32
                  _foo
00000000 4e56 fffc
                        ; linkw fp,#-4
00000004 1039 1234 5678
                          ; moveb @#12345678, d0
                          ; extbl d0
0000000a 49c0
                          ; unlk fp
0000000c 4e5e
0000000e 4e75
                          ; rts
```

Using co and an 88k, some instructions don't have enough space in them to represent the full address range, and pointers have to be loaded in two parts. So you'd get something like:

```
or.u r13, r0, hi 16(_foo+0x12345678)
Id.b r2, r13, Io16(_foo+0x12345678)
jmp r1
```

This should create two relocs, both pointing to _foo, and with 0x12340000 in their addend eld. The data would consist of:

```
RELOCATION RECORDS FOR [.text]:

offset type value

00000002 HVRT16 _foo+0x12340000

00000006 LVRT16 _foo+0x12340000

00000000 5da05678 ; or.u r13, r0, 0x5678

00000004 1c4d5678 ; ld.b r2, r13, 0x5678

00000008 f400c001 ; jmp r1
```

The relocation routine digs out the value from the data, adds it to the addend to get the original o set, and then adds the value of _foo. Note that all 32 bits have to be kept around somewhere, to cope with carry from bit 15 to bit 16.

One further example is the sparc and the a.out format. The sparc has a similar problem to the 88k, in that some instructions don't have room for an entire o set, but on the sparc the parts are created in odd sized lumps. The designers of the a.out format chose to not use the data within the section for storing part of the o set; all the o set is kept within the reloc. Anything in the data should be ignored.

```
save %sp, -112, %sp
sethi %hi (_foo+0x12345678), %g2
I dsb [%g2+%I o(_foo+0x12345678)], %i 0
ret
restore
```

Both relocs contain a pointer to foo, and the o sets contain junk.

```
RELOCATION RECORDS FOR [.text]:
offset type value
00000004 HI22 _foo+0x12345678
```

```
00000008 L010 _foo+0x12345678

00000000 9de3bf90 ; save %sp, -112, %sp

00000004 05000000 ; sethi %hi (_foo+0), %g2

00000008 f048a000 ; Idsb [%g2+%lo(_foo+0)], %i 0

0000000c 81c7e008 ; ret

00000010 81e80000 ; restore
```

howto

The howto eld can be imagined as a relocation instruction. It is a pointer to a structure which contains information on what to do with all of the other information in the reloc record and data section. A back end would normally have a relocation instruction set and turn relocations into pointers to the correct structure on input - but it would be possible to create each howto eld on demand.

2.10.1.1 enum complain_overflow

Indicates what sort of over ow checking should be done when performing a relocation.

```
enum complain_overflow
{
    /* Do not complain on overflow. */
    complain_overflow_dont,

    /* Complain if the value overflows when considered as a signed
        number one bit larger than the field. ie. A bitfield of N bits
        is allowed to represent -2**n to 2**n-1. */
    complain_overflow_bitfield,

    /* Complain if the value overflows when considered as a signed
        number. */
    complain_overflow_signed,

    /* Complain if the value overflows when considered as an
        unsigned number. */
    complain_overflow_unsigned
};
```

2.10.1.2 reloc_howto_type

The reloc_howto_type is a structure which contains all the information that libbfd needs to know to tie up a back end's data.

```
external idea of what a reloc number is stored in this field. For example, a PC relative word relocation in a coff environment has the type 023 - because that's what the outside world calls a R_PCRWORD reloc. */ unsigned int type;
```

- /* The value the final relocation is shifted right by. This drops
 unwanted data from the relocation. */
 unsigned int rightshift;
- /* The size of the item to be relocated. This is *not* a
 power-of-two measure. To get the number of bytes operated
 on by a type of relocation, use bfd_get_reloc_size. */
 int size;
- /* The number of bits in the item to be relocated. This is used
 when doing overflow checking. */
 unsigned int bitsize;
- /* The relocation is relative to the field being relocated. */bfd_boolean pc_relative;
- /* The bit position of the reloc value in the destination.
 The relocated value is left shifted by this amount. */
 unsigned int bitpos;
- /* What type of overflow error should be checked for when
 relocating. */
 enum complain_overflow complain_on_overflow;
- /* If this field is non null, then the supplied function is called rather than the normal function. This allows really strange relocation methods to be accommodated (e.g., i960 callj instructions). */
- bfd_reloc_status_type (*special_function)
 (bfd *, arelent *, struct bfd_symbol *, void *, asection *,
 bfd *, char **);
- /* The textual name of the relocation type. */
 char *name;
- /* Some formats record a relocation addend in the section contents rather than with the relocation. For ELF formats this is the distinction between USE_REL and USE_RELA (though the code checks for USE_REL == 1/0). The value of this field is TRUE if the addend is recorded with the section contents; when performing a partial link (Id -r) the section contents (the data) will be

modified. The value of this field is FALSE if addends are recorded with the relocation (in arelent addend); when performing a partial link the relocation will be modified.

All relocations for all ELF USE_RELA targets should set this field to FALSE (values of TRUE should be looked on with suspicion). However, the converse is not true: not all relocations of all ELF USE_REL targets set this field to TRUE. Why this is so is peculiar to each particular target. For relocs that aren't used in partial links (e.g. GOT stuff) it doesn't matter what this is set to. */bfd_boolean partial_inplace;

/* src_mask selects the part of the instruction (or data) to be used
in the relocation sum. If the target relocations don't have an
addend in the reloc, eg. ELF USE_REL, src_mask will normally equal
dst_mask to extract the addend from the section contents. If
relocations do have an addend in the reloc, eg. ELF USE_RELA, this
field should be zero. Non-zero values for ELF USE_RELA targets are
bogus as in those cases the value in the dst_mask part of the
section contents should be treated as garbage. */
bfd vma src mask;

```
/* dst_mask selects which parts of the instruction (or data) are
  replaced with a relocated value. */
bfd vma dst mask;
```

```
/* When some formats create PC relative instructions, they leave
    the value of the pc of the place being relocated in the offset
    slot of the instruction, so that a PC relative relocation can
    be made just by adding in an ordinary offset (e.g., sun3 a.out).
    Some formats leave the displacement part of an instruction
    empty (e.g., m88k bcs); this flag signals the fact. */
    bfd_boolean pcrel_offset;
}:
```

2.10.1.3 The HOWTO Macro

Description

The HOWTO de ne is horrible and will go away.

```
#define HOWTO(C, R, S, B, P, BI, O, SF, NAME, INPLACE, MASKSRC, MASKDST, PC) \■ { (unsigned) C, R, S, B, P, BI, O, SF, NAME, INPLACE, MASKSRC, MASKDST, PC }■
```

Description

And will be replaced with the totally magic way. But for the moment, we are compatible, so do it this way.

```
#define NEWHOWTO(FUNCTION, NAME, SIZE, REL, IN) \
HOWTO (O, O, SIZE, O, REL, O, complain_overflow_dont, FUNCTION, \
NAME, FALSE, O, O, IN)
```

```
This is used to II in an empty howto entry in an array.

#defi ne EMPTY_HOWTO(C) \
HOWTO ((C), 0, 0, 0, FALSE, 0, complain_overflow_dont, NULL, \
NULL, FALSE, 0, 0, FALSE)
```

Description

```
Helper routine to turn a symbol into a relocation value.
```

```
#define HOWTO_PREPARE(relocation, symbol)
{
   if (symbol != NULL)
   {
      if (bfd_is_com_section (symbol->section))
      {
        relocation = 0;
      }
      else
      {
        relocation = symbol->value;
      }
   }
}
```

2.10.1.4 bfd_get_reloc_size

Synopsis

```
unsigned int bfd_get_reloc_size (reloc_howto_type *);
```

Description

For a reloc_howto_type that operates on a xed number of bytes, this returns the number of bytes operated on.

2.10.1.5 arelent_chain

Description

```
How relocs are tied together in an asection:
```

```
typedef struct relent_chain
{
   arelent relent;
   struct relent_chain *next;
}
arelent_chain;
```

2.10.1.6 bfd_check_overflow

```
bfd_reloc_status_type bfd_check_overflow
  (enum complain_overflow how,
   unsigned int bitsize,
   unsigned int rightshift,
   unsigned int addrsize,
   bfd_vma relocation);
```

Perform over ow checking on *relocation* which has *bitsize* signi cant bits and will be shifted right by *rightshift* bits, on a machine with addresses containing *addrsize* signi cant bits. The result is either of bfd reloc ok or bfd reloc overflow.

2.10.1.7 bfd_reloc_offset_in_range

Synopsis

```
bfd_boolean bfd_reloc_offset_in_range
  (reloc_howto_type *howto,
    bfd *abfd,
    asection *section,
    bfd_size_type offset);
```

Description

Returns TRUE if the reloc described by *HOWTO* can be applied at *OFFSET* octets in *SECTION*.

2.10.1.8 bfd_perform_relocation

Synopsis

```
bfd_reloc_status_type bfd_perform_relocation
  (bfd *abfd,
    arelent *reloc_entry,
    void *data,
    asection *input_section,
    bfd *output_bfd,
    char **error_message);
```

Description

If <code>output_bfd</code> is supplied to this function, the generated image will be relocatable; the relocations are copied to the output—le after they have been changed to re ect the new state of the world. There are two ways of re—ecting the results of partial linkage in an output—le: by modifying the output data in place, and by modifying the relocation record. Some native formats (e.g., basic a.out and basic co—) have no way of specifying an addend in the relocation type, so the addend has to go in the output data. This is no big deal since in these formats the output data slot will always be big enough for the addend. Complex reloc types with addends were invented to solve just this problem. The <code>error_message</code> argument is set to an error message if this return <code>bfd_rel</code> oc_dangerous.

2.10.1.9 bfd_install_relocation

```
bfd_reloc_status_type bfd_install_relocation
```

```
(bfd *abfd,
  arelent *reloc_entry,
  void *data, bfd_vma data_start,
  asection *input_section,
  char **error_message);
```

This looks remarkably like bfd_perform_relocation, except it does not expect that the section contents have been led in. I.e., it's suitable for use when creating, rather than applying a relocation.

For now, this function should be considered reserved for the assembler.

2.10.2 The howto manager

When an application wants to create a relocation, but doesn't know what the target machine might call it, it can not out by using this bit of code.

2.10.2.1 bfd_reloc_code_type

Description

The insides of a reloc code. The idea is that, eventually, there will be one enumerator for every type of relocation we ever do. Pass one of these values to bfd_reloc_type_l ookup, and it'll return a howto pointer.

This does mean that the application must determine the correct enumerator value; you can't get a howto pointer from a random set of attributes.

Here are the possible values for enum bfd_rel oc_code_real:

```
BFD_RELOC_64
BFD_RELOC_32
BFD_RELOC_26
BFD_RELOC_24
BFD_RELOC_16
BFD_RELOC_14
BFD_RELOC_8
```

Basic absolute relocations of N bits.

```
BFD_RELOC_64_PCREL
BFD_RELOC_32_PCREL
BFD_RELOC_24_PCREL
BFD_RELOC_16_PCREL
BFD_RELOC_12_PCREL
BFD_RELOC_8 PCREL
```

PC-relative relocations. Sometimes these are relative to the address of the relocation itself; sometimes they are relative to the start of the section containing the relocation. It depends on the specient arget.

The 24-bit relocation is used in some Intel 960 con gurations.

```
BFD RELOC 32 SECREL
```

Section relative relocations. Some targets need this for DWARF2.

BFD_RELOC_32_GOT_PCREL BFD_RELOC_16_GOT_PCREL BFD RELOC 8 GOT PCREL BFD_RELOC_32_GOTOFF BFD_RELOC_16_GOTOFF BFD_RELOC_L016_G0T0FF BFD RELOC HI 16 GOTOFF BFD_RELOC_HI 16_S_GOTOFF BFD_RELOC_8_GOTOFF BFD_RELOC_64_PLT_PCREL BFD RELOC 32 PLT PCREL BFD_RELOC_24_PLT_PCREL BFD_RELOC_16_PLT_PCREL BFD_RELOC_8_PLT_PCREL BFD RELOC 64 PLTOFF BFD_RELOC_32_PLTOFF BFD_RELOC_16_PLT0FF BFD_RELOC_LO16_PLT0FF BFD_RELOC_HI 16_PLT0FF BFD_RELOC_HI 16_S_PLTOFF BFD_RELOC_8_PLTOFF For ELF.

BFD_RELOC_SI ZE32 BFD_RELOC_SI ZE64 Size relocations.

BFD RELOC 68K GLOB DAT BFD_RELOC_68K_JMP_SLOT BFD RELOC 68K RELATIVE BFD_RELOC_68K_TLS_GD32 BFD RELOC 68K TLS GD16 BFD_RELOC_68K_TLS_GD8 BFD RELOC 68K TLS LDM32 BFD_RELOC_68K_TLS_LDM16 BFD RELOC 68K TLS LDM8 BFD_RELOC_68K_TLS_LD032 BFD RELOC 68K TLS LD016 BFD RELOC 68K TLS LD08 BFD RELOC 68K TLS 1E32 BFD_RELOC_68K_TLS_IE16 BFD RELOC 68K TLS IE8 BFD RELOC 68K TLS LE32 BFD RELOC 68K TLS LE16 BFD RELOC 68K TLS LE8 Relocations used by 68K ELF. BFD_RELOC_32_BASEREL BFD_RELOC_16_BASEREL BFD_RELOC_LO16_BASEREL BFD_RELOC_HI16_BASEREL BFD_RELOC_HI16_S_BASEREL BFD_RELOC_8_BASEREL BFD_RELOC_RVA

Linkage-table relative.

BFD RELOC 8 FFnn

Absolute 8-bit relocation, but used to form an address like 0xFFnn.

BFD_RELOC_32_PCREL_S2 BFD_RELOC_16_PCREL_S2 BFD_RELOC_23_PCREL_S2

These PC-relative relocations are stored as word displacements { i.e., byte displacements shifted right two bits. The 30-bit word displacement (<<32_PCREL_S2>> { 32 bits, shifted 2) is used on the SPARC. (SPARC tools generally refer to this as <<WDISP30>>.) The signed 16-bit displacement is used on the MIPS, and the 23-bit displacement is used on the Alpha.

BFD_RELOC_HI 22 BFD_RELOC_L010

High 22 bits and low 10 bits of 32-bit value, placed into lower bits of the target word. These are used on the SPARC.

BFD_RELOC_GPREL16 BFD_RELOC_GPREL32

For systems that allocate a Global Pointer register, these are displacements o that register. These relocation types are handled specially, because the value the register will have is decided relatively late.

BFD RELOC 1960 CALLJ

Reloc types used for i960/b.out.

BFD RELOC ALPHA GPDISP HI16

Alpha ECOFF and ELF relocations. Some of these treat the symbol or "addend" in some special way. For GPDISP_HI16 ("gpdisp") relocations, the symbol is ignored when writing; when reading, it will be the absolute section symbol. The addend is the displacement in bytes of the "Ida" instruction from the "Idah" instruction (which is at the address of this reloc).

BFD_RELOC_ALPHA_GPDISP_L016

For GPDISP_LO16 ("ignore") relocations, the symbol is handled as with GPDISP_HI16 relocs. The addend is ignored when writing the relocations out, and is lled in with the le's GP value on reading, for convenience.

BFD RELOC ALPHA GPDISP

The ELF GPDISP relocation is exactly the same as the GPDISP_HI16 relocation except that there is no accompanying GPDISP_LO16 relocation.

BFD RELOC ALPHA LITERAL

BFD_RELOC_ALPHA_ELF_LITERAL

BFD_RELOC_ALPHA_LITUSE

The Alpha LITERAL/LITUSE relocs are produced by a symbol reference; the assembler turns it into a LDQ instruction to load the address of the symbol, and then IIs in a register in the real instruction.

The LITERAL reloc, at the LDQ instruction, refers to the .lita section symbol. The addend is ignored when writing, but is Iled in with the Ie's GP value on reading, for convenience, as with the GPDISP_LO16 reloc.

The ELF_LITERAL reloc is somewhere between 16_GOTOFF and GPDISP_LO16. It should refer to the symbol to be referenced, as with 16_GOTOFF, but it generates output not based on the position within the .got section, but relative to the GP value chosen for the le during the nal link stage.

The LITUSE reloc, on the instruction using the loaded address, gives information to the linker that it might be able to use to optimize away some literal section references. The symbol is ignored (read as the absolute section symbol), and the "addend" indicates the type of instruction using the register: 1 - "memory" fmt insn 2 - bytemanipulation (byte o set reg) 3 - jsr (target of branch)

BFD_RELOC_ALPHA_HINT

The HINT relocation indicates a value that should be Iled into the "hint" eld of a jmp/jsr/ret instruction, for possible branch- prediction logic which may be provided on some processors.

BFD RELOC ALPHA LINKAGE

The LINKAGE relocation outputs a linkage pair in the object le, which is lied by the linker.

BFD_RELOC_ALPHA_CODEADDR

The CODEADDR relocation outputs a STO_CA in the object le, which is lled by the linker.

BFD_RELOC_ALPHA_GPREL_HI 16

BFD RELOC ALPHA GPREL L016

The GPREL_HI/LO relocations together form a 32-bit o set from the GP register.

BFD RELOC ALPHA BRSGP

Like BFD_RELOC_23_PCREL_S2, except that the source and target must share a common GP, and the target address is adjusted for STO_ALPHA_STD_GPLOAD.

BFD RELOC ALPHA NOP

The NOP relocation outputs a NOP if the longword displacement between two procedure entry points is $< 2^21$.

BFD_RELOC_ALPHA_BSR

The BSR relocation outputs a BSR if the longword displacement between two procedure entry points is $< 2^21$.

BFD_RELOC_ALPHA_LDA

The LDA relocation outputs a LDA if the longword displacement between two procedure entry points is $< 2^16$.

BFD_RELOC_ALPHA_BOH

The BOH relocation outputs a BSR if the longword displacement between two procedure entry points is $< 2^21$, or else a hint.

BFD RELOC ALPHA TLSGD

BFD_RELOC_ALPHA_TLSLDM

BFD RELOC ALPHA DTPMOD64

BFD RELOC ALPHA GOTDTPREL16

BFD RELOC ALPHA TPREL16

Alpha thread-local storage relocations.

BFD RELOC MIPS JMP

BFD RELOC MICROMIPS JMP

The MIPS jump instruction.

BFD_RELOC_MI PS16_JMP

The MIPS16 jump instruction.

BFD RELOC MIPS16 GPREL

MIPS16 GP relative reloc.

BFD RELOC HI16

High 16 bits of 32-bit value; simple reloc.

BFD_RELOC_HI 16_S

High 16 bits of 32-bit value but the low 16 bits will be sign extended and added to form the nal result. If the low 16 bits form a negative number, we need to add one to the high value to compensate for the borrow when the low bits are added.

BFD RELOC LO16

Low 16 bits.

BFD_RELOC_HI 16_PCREL

High 16 bits of 32-bit pc-relative value

BFD_RELOC_HI 16_S_PCREL

High 16 bits of 32-bit pc-relative value, adjusted

BFD_RELOC_L016_PCREL

Low 16 bits of pc-relative value

BFD_RELOC_MI PS16_GOT16

BFD_RELOC_MI PS16_CALL16

Equivalent of BFD_RELOC_MIPS_*, but with the MIPS16 layout of 16-bit immediate elds

BFD RELOC MIPS16 HI16

MIPS16 high 16 bits of 32-bit value.

BFD_RELOC_MI PS16_HI 16_S

MIPS16 high 16 bits of 32-bit value but the low 16 bits will be sign extended and added to form the nal result. If the low 16 bits form a negative number, we need to add one to the high value to compensate for the borrow when the low bits are added.

BFD_RELOC_MI PS16_L016

MIPS16 low 16 bits.

BFD_RELOC_PPC64_TPREL16_HIGHA

BFD RELOC PPC64 DTPREL16 HIGH

BFD RELOC PPC64 DTPREL16 HIGHA

PowerPC and PowerPC64 thread-local storage relocations.

BFD_RELOC_I 370_D12

IBM 370/390 relocations

BFD RELOC CTOR

The type of reloc used to build a constructor table - at the moment probably a 32 bit wide absolute relocation, but the target can choose. It generally does map to one of the other relocation types.

BFD RELOC ARM PCREL BRANCH

ARM 26 bit pc-relative branch. The lowest two bits must be zero and are not stored in the instruction.

BFD_RELOC_ARM_PCREL_BLX

ARM 26 bit pc-relative branch. The lowest bit must be zero and is not stored in the instruction. The 2nd lowest bit comes from a 1 bit eld in the instruction.

BFD RELOC THUMB PCREL BLX

Thumb 22 bit pc-relative branch. The lowest bit must be zero and is not stored in the instruction. The 2nd lowest bit comes from a 1 bit eld in the instruction.

BFD RELOC ARM PCREL CALL

ARM 26-bit pc-relative branch for an unconditional BL or BLX instruction.

BFD_RELOC_ARM_PCREL_JUMP

ARM 26-bit pc-relative branch for B or conditional BL instruction.

BFD RELOC THUMB PCREL BRANCH7

BFD RELOC THUMB PCREL BRANCH9

BFD RELOC THUMB PCREL BRANCH12

BFD_RELOC_THUMB_PCREL_BRANCH20

BFD_RELOC_THUMB_PCREL_BRANCH23

BFD RELOC THUMB PCREL BRANCH25

Thumb 7-, 9-, 12-, 20-, 23-, and 25-bit pc-relative branches. The lowest bit must be zero and is not stored in the instruction. Note that the corresponding ELF R_ARM_THM_JUMPnn constant has an "nn" one smaller in all cases. Note further that BRANCH23 corresponds to R_ARM_THM_CALL.

BFD RELOC ARM OFFSET IMM

12-bit immediate o set, used in ARM-format ldr and str instructions.

BFD RELOC ARM THUMB OFFSET

5-bit immediate o set, used in Thumb-format ldr and str instructions.

BFD_RELOC_ARM_TARGET1

Pc-relative or absolute relocation depending on target. Used for entries in .init_array sections.

BFD RELOC ARM ROSEGREL32

Read-only segment base relative address.

BFD_RELOC_ARM_SBREL32

Data segment base relative address.

BFD RELOC ARM TARGET2

This reloc is used for references to RTTI data from exception handling tables. The actual de nition depends on the target. It may be a pc-relative or some form of GOT-indirect relocation.

BFD RELOC ARM PREL31

31-bit PC relative address.

BFD_RELOC_ARM_MOVW

BFD RELOC ARM MOVT

BFD_RELOC_ARM_MOVW_PCREL

BFD RELOC ARM MOVT PCREL

BFD_RELOC_ARM_THUMB_MOVW

BFD RELOC ARM THUMB MOVT

BFD RELOC ARM THUMB MOVW PCREL

BFD RELOC ARM THUMB MOVT PCREL

Low and High halfword relocations for MOVW and MOVT instructions.

BFD RELOC ARM JUMP SLOT

BFD RELOC ARM GLOB DAT

BFD_RELOC_ARM_GOT32

BFD RELOC ARM PLT32

BFD_RELOC_ARM_RELATIVE

BFD RELOC ARM GOTOFF

BFD_RELOC_ARM_GOTPC

BFD RELOC ARM GOT PREL

Relocations for setting up GOTs and PLTs for shared libraries.

BFD RELOC ARM TLS GD32

BFD_RELOC_ARM_TLS_LD032

BFD_RELOC_ARM_TLS_LDM32

BFD RELOC ARM TLS DTPOFF32

BFD ARELOC BFIN ADDR

ADI Black n arithmetic relocation.

BFD RELOC D10V 10 PCREL R

Mitsubishi D10V relocs. This is a 10-bit reloc with the right 2 bits assumed to be 0.

BFD_RELOC_D10V_10_PCREL_L

Mitsubishi D10V relocs. This is a 10-bit reloc with the right 2 bits assumed to be 0. This is the same as the previous reloc except it is in the left container, i.e., shifted left 15 bits.

BFD RELOC D10V 18

This is an 18-bit reloc with the right 2 bits assumed to be 0.

BFD_RELOC_D10V_18_PCREL

This is an 18-bit reloc with the right 2 bits assumed to be 0.

BFD RELOC D30V 6

Mitsubishi D30V relocs. This is a 6-bit absolute reloc.

BFD RELOC D30V 9 PCREL

This is a 6-bit pc-relative reloc with the right 3 bits assumed to be 0.

BFD_RELOC_D30V_9_PCREL_R

This is a 6-bit pc-relative reloc with the right 3 bits assumed to be 0. Same as the previous reloc but on the right side of the container.

BFD RELOC D30V 15

This is a 12-bit absolute reloc with the right 3 bitsassumed to be 0.

BFD_RELOC_D30V_15_PCREL

This is a 12-bit pc-relative reloc with the right 3 bits assumed to be 0.

BFD RELOC D30V 15 PCREL R

This is a 12-bit pc-relative reloc with the right 3 bits assumed to be 0. Same as the previous reloc but on the right side of the container.

BFD_RELOC_D30V_21

This is an 18-bit absolute reloc with the right 3 bits assumed to be 0.

BFD_RELOC_D30V_21_PCREL

This is an 18-bit pc-relative reloc with the right 3 bits assumed to be 0.

BFD RELOC D30V 21 PCREL R

This is an 18-bit pc-relative reloc with the right 3 bits assumed to be 0. Same as the previous reloc but on the right side of the container.

BFD RELOC D30V 32

This is a 32-bit absolute reloc.

BFD_RELOC_D30V_32_PCREL

This is a 32-bit pc-relative reloc.

BFD RELOC DLX HI16 S

DLX relocs

BFD RELOC DLX L016

DLX relocs

BFD_RELOC_DLX_JMP26

DLX relocs

BFD RELOC M32C HI8

BFD_RELOC_M32C_RL_JUMP

BFD RELOC M32C RL 1ADDR

BFD_RELOC_M32C_RL_2ADDR

Renesas M16C/M32C Relocations.

BFD RELOC M32R 24

Renesas M32R (formerly Mitsubishi M32R) relocs. This is a 24 bit absolute address.

BFD RELOC M32R 10 PCREL

This is a 10-bit pc-relative reloc with the right 2 bits assumed to be 0.

BFD RELOC M32R 18 PCREL

This is an 18-bit reloc with the right 2 bits assumed to be 0.

BFD_RELOC_M32R_26_PCREL

This is a 26-bit reloc with the right 2 bits assumed to be 0.

BFD_RELOC_M32R_HI16_ULO

This is a 16-bit reloc containing the high 16 bits of an address used when the lower 16 bits are treated as unsigned.

BFD_RELOC_M32R_HI 16_SLO

This is a 16-bit reloc containing the high 16 bits of an address used when the lower 16 bits are treated as signed.

BFD RELOC M32R L016

This is a 16-bit reloc containing the lower 16 bits of an address.

BFD_RELOC_M32R_SDA16

This is a 16-bit reloc containing the small data area o set for use in add3, load, and store instructions.

BFD RELOC M32R GOT24

BFD_RELOC_M32R_26_PLTREL

BFD_RELOC_M32R_COPY

BFD_RELOC_M32R_GLOB_DAT

BFD_RELOC_M32R_JMP_SLOT

BFD RELOC M32R RELATIVE

BFD_RELOC_M32R_GOTOFF

BFD_RELOC_M32R_GOTOFF_HI_ULO

BFD RELOC M32R GOTOFF HI SLO

BFD_RELOC_M32R_GOTOFF LO

BFD RELOC M32R GOTPC24

BFD_RELOC_M32R_GOT16_HI_ULO

BFD_RELOC_M32R_GOT16_HI_SLO

BFD RELOC M32R GOT16 LO

BFD RELOC M32R GOTPC HI ULO

BFD RELOC M32R GOTPC HI SLO

BFD RELOC M32R GOTPC LO

For PIC.

BFD RELOC NDS32 20

NDS32 relocs. This is a 20 bit absolute address.

BFD_RELOC_NDS32_9_PCREL

This is a 9-bit pc-relative reloc with the right 1 bit assumed to be 0.

BFD RELOC NDS32 WORD 9 PCREL

This is a 9-bit pc-relative reloc with the right 1 bit assumed to be 0.

BFD RELOC NDS32 15 PCREL

This is an 15-bit reloc with the right 1 bit assumed to be 0.

BFD RELOC NDS32 17 PCREL

This is an 17-bit reloc with the right 1 bit assumed to be 0.

BFD_RELOC_NDS32_25_PCREL

This is a 25-bit reloc with the right 1 bit assumed to be 0.

BFD RELOC NDS32 HI20

This is a 20-bit reloc containing the high 20 bits of an address used with the lower 12 bits

BFD RELOC NDS32 L012S3

This is a 12-bit reloc containing the lower 12 bits of an address then shift right by 3. This is used with Idi,sdi...

BFD RELOC NDS32 L012S2

This is a 12-bit reloc containing the lower 12 bits of an address then shift left by 2. This is used with lwi,swi...

BFD_RELOC_NDS32_L012S1

This is a 12-bit reloc containing the lower 12 bits of an address then shift left by 1. This is used with Ihi,shi...

BFD RELOC NDS32 L012S0

This is a 12-bit reloc containing the lower 12 bits of an address then shift left by 0. This is used with Ibisbi...

BFD RELOC NDS32 L012SO ORI

This is a 12-bit reloc containing the lower 12 bits of an address then shift left by 0. This is only used with branch relaxations

BFD RELOC NDS32 SDA15S3

This is a 15-bit reloc containing the small data area 18-bit signed o set and shift left by 3 for use in Idi, sdi...

BFD RELOC NDS32 SDA15S2

This is a 15-bit reloc containing the small data area 17-bit signed o set and shift left by 2 for use in lwi, swi...

BFD RELOC NDS32 SDA15S1

This is a 15-bit reloc containing the small data area 16-bit signed o set and shift left by 1 for use in lhi, shi...

BFD RELOC NDS32 SDA15SO

This is a 15-bit reloc containing the small data area 15-bit signed o set and shift left by 0 for use in lbi, sbi...

BFD RELOC NDS32 SDA16S3

This is a 16-bit reloc containing the small data area 16-bit signed o set and shift left by 3

BFD_RELOC_NDS32_SDA17S2

This is a 17-bit reloc containing the small data area 17-bit signed o set and shift left by 2 for use in lwi.gp, swi.gp...

BFD RELOC NDS32 SDA18S1

This is a 18-bit reloc containing the small data area 18-bit signed o set and shift left by 1 for use in lhi.gp, shi.gp...

BFD RELOC NDS32 SDA19SO

This is a 19-bit reloc containing the small data area 19-bit signed o set and shift left by 0 for use in lbi.gp, sbi.gp...

relaxation relative relocation types

BFD_RELOC_NDS32_25_ABS

This is a 25 bit absolute address.

BFD RELOC NDS32 DATA

BFD_RELOC_NDS32_TRAN

BFD RELOC NDS32 171FC PCREL

BFD_RELOC_NDS32_101 FCU_PCREL

For ex9 and ifc using.

BFD RELOC NDS32 TPOFF

BFD_RELOC_NDS32_TLS_LE_HI 20

BFD_RELOC_NDS32_TLS_LE_L012

BFD_RELOC_NDS32_TLS_LE_ADD

BFD RELOC NDS32 TLS LE LS

BFD_RELOC_NDS32_GOTTPOFF

BFD_RELOC_NDS32_TLS_IE_HI20

BFD_RELOC_NDS32_TLS_I E_L012S2

BFD_RELOC_NDS32_TLS_TP0FF

BFD_RELOC_NDS32_TLS_LE_20

BFD_RELOC_NDS32_TLS_LE_15S0

BFD RELOC NDS32 TLS LE 15S1

BFD_RELOC_NDS32_TLS_LE_15S2 For TLS.

BFD RELOC V850 9 PCREL

This is a 9-bit reloc

BFD_RELOC_V850_22_PCREL

This is a 22-bit reloc

BFD RELOC V850 SDA 16 16 OFFSET

This is a 16 bit o set from the short data area pointer.

BFD_RELOC_V850_SDA_15_16_OFFSET

This is a 16 bit o set (of which only 15 bits are used) from the short data area pointer.

BFD_RELOC_V850_ZDA_16_16_0FFSET

This is a 16 bit o set from the zero data area pointer.

BFD RELOC_V850_ZDA_15_16_0FFSET

This is a 16 bit o set (of which only 15 bits are used) from the zero data area pointer.

BFD RELOC V850 TDA 6 8 OFFSET

This is an 8 bit o set (of which only 6 bits are used) from the tiny data area pointer.

BFD_RELOC_V850_TDA_7_8_OFFSET

This is an 8bit o set (of which only 7 bits are used) from the tiny data area pointer.

BFD RELOC V850 TDA 7 7 OFFSET

This is a 7 bit o set from the tiny data area pointer.

BFD_RELOC_V850_TDA_16_16_0FFSET

This is a 16 bit o set from the tiny data area pointer.

BFD_RELOC_V850_TDA_4_5_OFFSET

This is a 5 bit o set (of which only 4 bits are used) from the tiny data area pointer.

BFD_RELOC_V850_TDA_4_4_OFFSET

This is a 4 bit o set from the tiny data area pointer.

BFD RELOC V850 SDA 16 16 SPLIT OFFSET

This is a 16 bit o set from the short data area pointer, with the bits placed non-contiguously in the instruction.

BFD_RELOC_V850_ZDA_16_16_SPLIT_OFFSET

This is a 16 bit o set from the zero data area pointer, with the bits placed non-contiguously in the instruction.

BFD_RELOC_V850_CALLT_6_7_OFFSET

This is a 6 bit o set from the call table base pointer.

BFD_RELOC_V850_CALLT_16_16_0FFSET

This is a 16 bit o set from the call table base pointer.

BFD RELOC V850 LONGCALL

Used for relaxing indirect function calls.

BFD RELOC V850 LONGJUMP

Used for relaxing indirect jumps.

BFD RELOC V850 ALIGN

Used to maintain alignment whilst relaxing.

BFD RELOC V850_L016_SPLIT_OFFSET

This is a variation of BFD_RELOC_LO16 that can be used in v850e ld.bu instructions.

BFD_RELOC_V850_16_PCREL

This is a 16-bit reloc.

BFD_RELOC_V850_17_PCREL

This is a 17-bit reloc.

BFD RELOC V850 23

This is a 23-bit reloc.

BFD RELOC V850 32 PCREL

This is a 32-bit reloc.

BFD_RELOC_V850_32_ABS

This is a 32-bit reloc.

BFD RELOC V850 16 SPLIT OFFSET

This is a 16-bit reloc.

- BFD_RELOC_V850_16_S1 This is a 16-bit reloc.
- BFD_RELOC_V850_L016_S1 Low 16 bits. 16 bit shifted by 1.
- BFD_RELOC_V850_CALLT_15_16_0FFSET

 This is a 16 bit o set from the call table base pointer.
- BFD_RELOC_V850_32_GOTPCREL DSO relocations.
- BFD_RELOC_V850_16_GOT DSO relocations.
- BFD_RELOC_V850_32_GOT DSO relocations.
- BFD_RELOC_V850_22_PLT_PCREL DSO relocations.
- BFD_RELOC_V850_32_PLT_PCREL DSO relocations.
- BFD_RELOC_V850_COPY DSO relocations.
- BFD_RELOC_V850_GLOB_DAT DSO relocations.
- BFD_RELOC_V850_JMP_SLOT DSO relocations.
- BFD_RELOC_V850_RELATIVE DSO relocations.
- BFD_RELOC_V850_16_GOTOFF DSO relocations.
- BFD_RELOC_V850_32_G0T0FF DSO relocations.
- BFD_RELOC_V850_CODE start code.
- BFD_RELOC_V850_DATA start data in text.
- BFD_RELOC_TIC30_LDP

This is a 8bit DP reloc for the tms320c30, where the most signi cant 8 bits of a 24 bit word are placed into the least signi cant 8 bits of the opcode.

BFD_RELOC_TIC54X_PARTLS7

This is a 7bit reloc for the tms320c54x, where the least signi cant 7 bits of a 16 bit word are placed into the least signi cant 7 bits of the opcode.

BFD RELOC TIC54X PARTMS9

This is a 9bit DP reloc for the tms320c54x, where the most signicant 9 bits of a 16 bit word are placed into the least signicant 9 bits of the opcode.

BFD RELOC TIC54X 23

This is an extended address 23-bit reloc for the tms320c54x.

BFD_RELOC_TIC54X_16_0F_23

This is a 16-bit reloc for the tms320c54x, where the least signicant 16 bits of a 23-bit extended address are placed into the opcode.

BFD_RELOC_TIC54X_MS7_0F_23

This is a reloc for the tms320c54x, where the most signi cant 7 bits of a 23-bit extended address are placed into the opcode.

BFD_RELOC_C6000_FPHEAD

BFD_RELOC_C6000_NOCMP

TMS320C6000 relocations.

BFD_RELOC_FR30_48

This is a 48 bit reloc for the FR30 that stores 32 bits.

BFD RELOC FR30 20

This is a 32 bit reloc for the FR30 that stores 20 bits split up into two sections.

BFD RELOC FR30 6 IN 4

This is a 16 bit reloc for the FR30 that stores a 6 bit word o set in 4 bits.

BFD_RELOC_FR30_8_IN_8

This is a 16 bit reloc for the FR30 that stores an 8 bit byte o set into 8 bits.

BFD RELOC FR30 9 IN 8

This is a 16 bit reloc for the FR30 that stores a 9 bit short o set into 8 bits.

BFD_RELOC_FR30_10_I N_8

This is a 16 bit reloc for the FR30 that stores a 10 bit word o set into 8 bits.

BFD_RELOC_FR30_9_PCREL

This is a 16 bit reloc for the FR30 that stores a 9 bit pc relative short o set into 8 bits.

BFD RELOC FR30 12 PCREL

This is a 16 bit reloc for the FR30 that stores a 12 bit pc relative short o set into 11 bits.

Imagination Technologies Meta relocations.

BFD RELOC MMIX GETA

BFD_RELOC_MMI X_GETA_1

BFD RELOC MMIX GETA 2

BFD_RELOC_MMIX_GETA_3

These are relocations for the GETA instruction.

BFD_RELOC_MMI X_CBRANCH

BFD RELOC MMIX CBRANCH J

BFD_RELOC_MMI X_CBRANCH_1

BFD RELOC MMIX CBRANCH 2

BFD RELOC MMIX CBRANCH 3

These are relocations for a conditional branch instruction.

BFD_RELOC_MMIX_PUSHJ

BFD RELOC MMIX PUSHJ 1

BFD_RELOC_MMI X_PUSHJ_2

BFD_RELOC_MMI X_PUSHJ_3

BFD RELOC MMIX PUSHJ STUBBABLE

These are relocations for the PUSHJ instruction.

BFD RELOC MMIX JMP

BFD RELOC MMIX JMP 1

BFD_RELOC_MMI X_JMP_2

BFD_RELOC_MMIX_JMP_3

These are relocations for the JMP instruction.

BFD_RELOC_MMI X_ADDR19

This is a relocation for a relative address as in a GETA instruction or a branch.

BFD RELOC MMIX ADDR27

This is a relocation for a relative address as in a JMP instruction.

BFD RELOC MMIX REG OR BYTE

This is a relocation for an instruction eld that may be a general register or a value 0..255.

BFD RELOC MMIX REG

This is a relocation for an instruction eld that may be a general register.

BFD_RELOC_MMI X_BASE_PLUS_OFFSET

This is a relocation for two instruction elds holding a register and an o set, the equivalent of the relocation.

BFD_RELOC_MMIX_LOCAL

This relocation is an assertion that the expression is not allocated as a global register. It does not modify contents.

BFD RELOC AVR 7 PCREL

This is a 16 bit reloc for the AVR that stores 8 bit pc relative short o set into 7 bits.

BFD_RELOC_AVR_13_PCREL

This is a 16 bit reloc for the AVR that stores 13 bit pc relative short o set into 12 bits.

BFD RELOC AVR 16 PM

This is a 16 bit reloc for the AVR that stores 17 bit value (usually program memory address) into 16 bits.

BFD_RELOC_AVR_LO8_LDI

This is a 16 bit reloc for the AVR that stores 8 bit value (usually data memory address) into 8 bit immediate value of LDI insn.

BFD_RELOC_AVR_HI8_LDI

This is a 16 bit reloc for the AVR that stores 8 bit value (high 8 bit of data memory address) into 8 bit immediate value of LDI insn.

BFD RELOC AVR HH8 LDI

This is a 16 bit reloc for the AVR that stores 8 bit value (most high 8 bit of program memory address) into 8 bit immediate value of LDI insn.

BFD RELOC AVR MS8 LDI

This is a 16 bit reloc for the AVR that stores 8 bit value (most high 8 bit of 32 bit value) into 8 bit immediate value of LDI insn.

BFD_RELOC_AVR_LO8_LDI_NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (usually data memory address) into 8 bit immediate value of SUBI insn.

BFD RELOC AVR HI8 LDI NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (high 8 bit of data memory address) into 8 bit immediate value of SUBI insn.

BFD_RELOC_AVR_HH8_LDI_NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (most high 8 bit of program memory address) into 8 bit immediate value of LDI or SUBI insn.

BFD RELOC AVR MS8 LDI NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (msb of 32 bit value) into 8 bit immediate value of LDI insn.

BFD_RELOC_AVR_LO8_LDI_PM

This is a 16 bit reloc for the AVR that stores 8 bit value (usually command address) into 8 bit immediate value of LDI insn.

BFD RELOC AVR LO8 LDI GS

This is a 16 bit reloc for the AVR that stores 8 bit value (command address) into 8 bit immediate value of LDI insn. If the address is beyond the 128k boundary, the linker inserts a jump stub for this reloc in the lower 128k.

BFD_RELOC_AVR_HI8_LDI_PM

This is a 16 bit reloc for the AVR that stores 8 bit value (high 8 bit of command address) into 8 bit immediate value of LDI insn.

BFD_RELOC_AVR_HI8_LDI_GS

This is a 16 bit reloc for the AVR that stores 8 bit value (high 8 bit of command address) into 8 bit immediate value of LDI insn. If the address is beyond the 128k boundary, the linker inserts a jump stub for this reloc below 128k.

BFD RELOC AVR HH8 LDI PM

This is a 16 bit reloc for the AVR that stores 8 bit value (most high 8 bit of command address) into 8 bit immediate value of LDI insn.

BFD RELOC AVR LO8 LDI PM NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (usually command address) into 8 bit immediate value of SUBI insn.

BFD RELOC AVR HI8 LDI PM NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (high 8 bit of 16 bit command address) into 8 bit immediate value of SUBI insn.

BFD RELOC AVR HH8 LDI PM NEG

This is a 16 bit reloc for the AVR that stores negated 8 bit value (high 6 bit of 22 bit command address) into 8 bit immediate value of SUBI insn.

BFD RELOC AVR CALL

This is a 32 bit reloc for the AVR that stores 23 bit value into 22 bits.

BFD RELOC AVR LDI

This is a 16 bit reloc for the AVR that stores all needed bits for absolute addressing with Idi with over ow check to linktime

BFD RELOC AVR 6

This is a 6 bit reloc for the AVR that stores o set for Idd/std instructions

BFD_RELOC_AVR_6_ADIW

This is a 6 bit reloc for the AVR that stores o set for adiw/sbiw instructions

BFD RELOC AVR 8 LO

This is a 8 bit reloc for the AVR that stores bits 0..7 of a symbol in .byte lo8(symbol)

BFD RELOC AVR 8 HI

This is a 8 bit reloc for the AVR that stores bits 8..15 of a symbol in .byte hi8(symbol)

BFD RELOC AVR 8 HLO

This is a 8 bit reloc for the AVR that stores bits 16..23 of a symbol in .byte hlo8(symbol)

BFD RELOC AVR DIFF8

BFD RELOC AVR DIFF16

BFD RELOC AVR DIFF32

AVR relocations to mark the di erence of two local symbols. These are only needed to support linker relaxation and can be ignored when not relaxing. The eld is set to the value of the di erence assuming no relaxation. The relocation encodes the position of the second symbol so the linker can determine whether to adjust the eld value.

BFD RELOC AVR LDS STS 16

This is a 7 bit reloc for the AVR that stores SRAM address for 16bit Ids and sts instructions supported only tiny core.

BFD_RELOC_AVR_PORT6

This is a 6 bit reloc for the AVR that stores an I/O register number for the IN and OUT instructions

BFD RELOC AVR PORT5

This is a 5 bit reloc for the AVR that stores an I/O register number for the SBIC, SBIS, SBI and CBI instructions

BFD_RELOC_IP2K_PC_SKIP

Scenix IP2K - even/odd PC modi er to modify snb pcl.0

BFD_RELOC_I P2K_TEXT

Scenix IP2K - 16 bit word address in text section.

BFD_RELOC_IP2K_FR_OFFSET

Scenix IP2K - 7-bit sp or dp o set

BFD RELOC VPE4KMATH DATA

BFD RELOC VPE4KMATH INSN

Scenix VPE4K coprocessor - data/insn-space addressing

BFD_RELOC_VTABLE_INHERIT

BFD_RELOC_VTABLE_ENTRY

These two relocations are used by the linker to determine which of the entries in a C++ virtual function table are actually used. When the {gc-sections option is given, the linker will zero out the entries that are not used, so that the code for those functions need not be included in the output.

VTABLE_INHERIT is a zero-space relocation used to describe to the linker the inheritance tree of a C++ virtual function table. The relocation's symbol should be the parent class' vtable, and the relocation should be located at the child vtable.

VTABLE_ENTRY is a zero-space relocation that describes the use of a virtual function table entry. The reloc's symbol should refer to the table of the class mentioned in the code. O of that base, an o set describes the entry that is being used. For Rela hosts, this o set is stored in the reloc's addend. For Rel hosts, we are forced to put this o set in the reloc's section o set.

- BFD_RELOC_M68HC11_HI8

Intel IA64 Relocations.

Motorola 68HC11 reloc. This is the 8 bit high part of an absolute address.

BFD RELOC M68HC11 L08

Motorola 68HC11 reloc. This is the 8 bit low part of an absolute address.

BFD RELOC M68HC11 3B

Motorola 68HC11 reloc. This is the 3 bit of a value.

BFD_RELOC_M68HC11_RL_JUMP

Motorola 68HC11 reloc. This reloc marks the beginning of a jump/call instruction. It is used for linker relaxation to correctly identify beginning of instruction and change some branches to use PC-relative addressing mode.

BFD RELOC M68HC11 RL GROUP

Motorola 68HC11 reloc. This reloc marks a group of several instructions that gcc generates and for which the linker relaxation pass can modify and/or remove some of them.

BFD_RELOC_M68HC11_L016

Motorola 68HC11 reloc. This is the 16-bit lower part of an address. It is used for 'call' instruction to specify the symbol address without any special transformation (due to memory bank window).

BFD_RELOC_M68HC11_PAGE

Motorola 68HC11 reloc. This is a 8-bit reloc that speci es the page number of an address. It is used by 'call' instruction to specify the page number of the symbol.

BFD_RELOC_M68HC11_24

Motorola 68HC11 reloc. This is a 24-bit reloc that represents the address with a 16-bit value and a 8-bit page number. The symbol address is transformed to follow the 16K memory bank of 68HC12 (seen as mapped in the window).

BFD RELOC M68HC12 5B

Motorola 68HC12 reloc. This is the 5 bits of a value.

BFD RELOC XGATE RL JUMP

Freescale XGATE reloc. This reloc marks the beginning of a bra/jal instruction.

BFD RELOC XGATE RL GROUP

Freescale XGATE reloc. This reloc marks a group of several instructions that gcc generates and for which the linker relaxation pass can modify and/or remove some of them.

BFD RELOC XGATE L016

Freescale XGATE reloc. This is the 16-bit lower part of an address. It is used for the '16-bit' instructions.

BFD_RELOC_XGATE_GPAGE

Freescale XGATE reloc.

BFD RELOC XGATE 24

Freescale XGATE reloc.

BFD RELOC XGATE PCREL 9

Freescale XGATE reloc. This is a 9-bit pc-relative reloc.

BFD RELOC XGATE PCREL 10

Freescale XGATE reloc. This is a 10-bit pc-relative reloc.

BFD RELOC XGATE IMM8 LO

Freescale XGATE reloc. This is the 16-bit lower part of an address. It is used for the '16-bit' instructions.

BFD RELOC XGATE IMM8 HI

Freescale XGATE reloc. This is the 16-bit higher part of an address. It is used for the '16-bit' instructions.

BFD RELOC XGATE IMM3

Freescale XGATE reloc. This is a 3-bit pc-relative reloc.

BFD RELOC XGATE IMM4

Freescale XGATE reloc. This is a 4-bit pc-relative reloc.

BFD_RELOC_XGATE_IMM5

Freescale XGATE reloc. This is a 5-bit pc-relative reloc.

BFD RELOC M68HC12 9B

Motorola 68HC12 reloc. This is the 9 bits of a value.

BFD RELOC M68HC12 16B

Motorola 68HC12 reloc. This is the 16 bits of a value.

BFD_RELOC_M68HC12_9_PCREL

Motorola 68HC12/XGATE reloc. This is a PCREL9 branch.

BFD RELOC M68HC12 10 PCREL

Motorola 68HC12/XGATE reloc. This is a PCREL10 branch.

BFD_RELOC_M68HC12_L08XG

Motorola 68HC12/XGATE reloc. This is the 8 bit low part of an absolute address and immediately precedes a matching HI8XG part.

BFD RELOC M68HC12 HI8XG

Motorola 68HC12/XGATE reloc. This is the 8 bit high part of an absolute address and immediately follows a matching LO8XG part.

BFD_RELOC_NI OS2_R2_T1X1I 6_2

Relocations used by the Altera Nios II core.

BFD RELOC PRU U16

PRU LDI 16-bit unsigned data-memory relocation.

BFD RELOC PRU U16 PMEMIMM

PRU LDI 16-bit unsigned instruction-memory relocation.

BFD_RELOC_PRU_LDI 32

PRU relocation for two consecutive LDI load instructions that load a 32 bit value into a register. If the higher bits are all zero, then the second instruction may be relaxed.

BFD_RELOC_PRU_S10_PCREL

PRU QBBx 10-bit signed PC-relative relocation.

BFD_RELOC_PRU_U8_PCREL

PRU 8-bit unsigned relocation used for the LOOP instruction.

BFD_RELOC_PRU_32_PMEM BFD_RELOC_PRU_16_PMEM

PRU Program Memory relocations. Used to convert from byte addressing to 32-bit word addressing.

BFD_RELOC_PRU_GNU_DIFF8
BFD_RELOC_PRU_GNU_DIFF16
BFD_RELOC_PRU_GNU_DIFF32
BFD_RELOC_PRU_GNU_DIFF16_PMEM
BFD_RELOC_PRU_GNU_DIFF32_PMEM

PRU relocations to mark the di erence of two local symbols. These are only needed to support linker relaxation and can be ignored when not relaxing. The eld is set to the value of the di erence assuming no relaxation. The relocation encodes the position of the second symbol so the linker can determine whether to adjust the eld value. The PMEM variants encode the word di erence, instead of byte di erence between symbols.

BFD_RELOC_I Q2000_OFFSET_16
BFD_RELOC_I Q2000_OFFSET_21
BFD_RELOC_I Q2000_UHI 16
IQ2000 Relocations.

BFD RELOC XTENSA RTLD

Special Xtensa relocation used only by PLT entries in ELF shared objects to indicate that the runtime linker should set the value to one of its own internal functions or data structures.

BFD_RELOC_XTENSA_GLOB_DAT BFD_RELOC_XTENSA_JMP_SLOT BFD_RELOC_XTENSA_RELATIVE

Xtensa relocations for ELF shared objects.

BFD RELOC XTENSA PLT

Xtensa relocation used in ELF object les for symbols that may require PLT entries. Otherwise, this is just a generic 32-bit relocation.

BFD_RELOC_XTENSA_DI FF8 BFD_RELOC_XTENSA_DI FF16 BFD_RELOC_XTENSA_DI FF32

Xtensa relocations to mark the difference of two local symbols. These are only needed to support linker relaxation and can be ignored when not relaxing. The field is set to the value of the difference assuming no relaxation. The relocation encodes the position of the first symbol so the linker can determine whether to adjust the field value.

BFD_RELOC_XTENSA_SLOTO_OP
BFD_RELOC_XTENSA_SLOT1_OP
BFD_RELOC_XTENSA_SLOT2_OP
BFD_RELOC_XTENSA_SLOT3_OP
BFD_RELOC_XTENSA_SLOT4_OP
BFD_RELOC_XTENSA_SLOT5_OP
BFD_RELOC_XTENSA_SLOT6_OP
BFD_RELOC_XTENSA_SLOT7_OP
BFD_RELOC_XTENSA_SLOT7_OP
BFD_RELOC_XTENSA_SLOT9_OP
BFD_RELOC_XTENSA_SLOT9_OP
BFD_RELOC_XTENSA_SLOT10_OP
BFD_RELOC_XTENSA_SLOT11_OP
BFD_RELOC_XTENSA_SLOT11_OP
BFD_RELOC_XTENSA_SLOT112_OP
BFD_RELOC_XTENSA_SLOT13_OP
BFD_RELOC_XTENSA_SLOT14_OP

Generic Xtensa relocations for instruction operands. Only the slot number is encoded in the relocation. The relocation applies to the last PC-relative immediate operand, or if there are no PC-relative immediates, to the last immediate operand.

BFD_RELOC_XTENSA_SLOTO_ALT BFD_RELOC_XTENSA_SLOT1_ALT BFD_RELOC_XTENSA_SLOT2_ALT BFD_RELOC_XTENSA_SLOT3_ALT BFD_RELOC_XTENSA_SLOT4_ALT BFD_RELOC_XTENSA_SLOT5_ALT BFD_RELOC_XTENSA_SLOT6_ALT BFD_RELOC_XTENSA_SLOT7_ALT

BFD_RELOC_XTENSA_SLOT8_ALT

BFD_RELOC_XTENSA_SLOT9_ALT

BFD_RELOC_XTENSA_SLOT10_ALT

BFD_RELOC_XTENSA_SLOT11_ALT

BFD_RELOC_XTENSA_SLOT12_ALT

BFD_RELOC_XTENSA_SLOT13_ALT BFD_RELOC_XTENSA_SLOT14_ALT

Alternate Xtensa relocations. Only the slot is encoded in the relocation. The meaning of these relocations is opcode-speci c.

BFD RELOC XTENSA OPO

BFD_RELOC_XTENSA_OP1

BFD RELOC XTENSA OP2

Xtensa relocations for backward compatibility. These have all been replaced by BFD_RELOC_XTENSA_SLOT0_OP.

BFD RELOC XTENSA ASM EXPAND

Xtensa relocation to mark that the assembler expanded the instructions from an original target. The expansion size is encoded in the reloc size.

BFD_RELOC_XTENSA_ASM_SIMPLIFY

Xtensa relocation to mark that the linker should simplify assembler-expanded instructions. This is commonly used internally by the linker after analysis of a BFD_RELOC_XTENSA_ASM_EXPAND.

BFD_RELOC_XTENSA_TLSDESC_FN

BFD RELOC XTENSA TLSDESC ARG

BFD_RELOC_XTENSA_TLS_DTPOFF

BFD_RELOC_XTENSA_TLS_TPOFF

BFD_RELOC_XTENSA_TLS_FUNC

BFD_RELOC_XTENSA_TLS_ARG

BFD_RELOC_XTENSA_TLS_CALL

Xtensa TLS relocations.

BFD RELOC Z80 DISP8

8 bit signed o set in (ix+d) or (iy+d).

BFD RELOC Z8K DISP7

DJNZ o set.

BFD_RELOC_Z8K_CALLR

CALR o set.

BFD RELOC Z8K IMM4L

4 bit value.

BFD RELOC LM32 CALL

BFD_RELOC_LM32_BRANCH

BFD RELOC LM32 16 GOT

BFD_RELOC_LM32_GOTOFF_HI 16

BFD_RELOC_LM32_GOTOFF_L016

BFD RELOC LM32 COPY

BFD_RELOC_LM32_GLOB_DAT

BFD_RELOC_LM32_JMP_SLOT

BFD_RELOC_LM32_RELATIVE

Lattice Mico32 relocations.

BFD RELOC MACH O SECTDIFF

Di erence between two section addreses. Must be followed by a BFD_RELOC_MACH_O_PAIR.

BFD_RELOC_MACH_O_LOCAL_SECTDIFF

Like BFD_RELOC_MACH_O_SECTDIFF but with a local symbol.

BFD RELOC MACH O PAIR

Pair of relocation. Contains the rst symbol.

BFD_RELOC_MACH_O_SUBTRACTOR32

Symbol will be substracted. Must be followed by a BFD_RELOC_32.

BFD_RELOC_MACH_O_SUBTRACTOR64

Symbol will be substracted. Must be followed by a BFD_RELOC_64.

BFD RELOC MACH 0 X86 64 BRANCH32

BFD_RELOC_MACH_0_X86_64_BRANCH8

PCREL relocations. They are marked as branch to create PLT entry if required.

BFD RELOC MACH O X86 64 GOT

Used when referencing a GOT entry.

BFD RELOC MACH O X86 64 GOT LOAD

Used when loading a GOT entry with movq. It is specially marked so that the linker could optimize the movq to a leaq if possible.

BFD_RELOC_MACH_0_X86_64_PCREL32_1

Same as BFD_RELOC_32_PCREL but with an implicit -1 addend.

BFD RELOC MACH 0 X86 64 PCREL32 2

Same as BFD_RELOC_32_PCREL but with an implicit -2 addend.

BFD RELOC MACH O X86 64 PCREL32 4

Same as BFD_RELOC_32_PCREL but with an implicit -4 addend.

BFD_RELOC_MACH_O_ARM64_ADDEND

Addend for PAGE or PAGEOFF.

BFD_RELOC_MACH_O_ARM64_GOT_LOAD_PAGE21

Relative o set to page of GOT slot.

BFD RELOC MACH O ARM64 GOT LOAD PAGEOFF12

Relative o set within page of GOT slot.

BFD_RELOC_MACH_O_ARM64_POINTER_TO_GOT

Address of a GOT entry.

BFD RELOC MICROBLAZE 32 LO

This is a 32 bit reloc for the microblaze that stores the low 16 bits of a value

BFD_RELOC_MI CROBLAZE_32_LO_PCREL

This is a 32 bit pc-relative reloc for the microblaze that stores the low 16 bits of a value

BFD_RELOC_MI CROBLAZE_32_ROSDA

This is a 32 bit reloc for the microblaze that stores a value relative to the read-only small data area anchor

BFD_RELOC_MI CROBLAZE_32_RWSDA

This is a 32 bit reloc for the microblaze that stores a value relative to the read-write small data area anchor

BFD_RELOC_MI CROBLAZE_32_SYM_OP_SYM

This is a 32 bit reloc for the microblaze to handle expressions of the form "Symbol Op Symbol"

BFD_RELOC_MI CROBLAZE_64_NONE

This is a 64 bit reloc that stores the 32 bit pc relative value in two words (with an imm instruction). No relocation is done here - only used for relaxing

BFD_RELOC_MI CROBLAZE_64_GOTPC

This is a 64 bit reloc that stores the 32 bit pc relative value in two words (with an imm instruction). The relocation is PC-relative GOT o set

BFD RELOC MICROBLAZE 64 GOT

This is a 64 bit reloc that stores the 32 bit pc relative value in two words (with an imm instruction). The relocation is GOT o set

BFD_RELOC_MI CROBLAZE_64_PLT

This is a 64 bit reloc that stores the 32 bit pc relative value in two words (with an imm instruction). The relocation is PC-relative o set into PLT

BFD_RELOC_MI CROBLAZE_64_GOTOFF

This is a 64 bit reloc that stores the 32 bit GOT relative value in two words (with an imm instruction). The relocation is relative o set from _GLOBAL_OFFSET_TABLE_

BFD_RELOC_MI CROBLAZE_32_GOTOFF

This is a 32 bit reloc that stores the 32 bit GOT relative value in a word. The relocation is relative o set from

BFD RELOC MICROBLAZE COPY

This is used to tell the dynamic linker to copy the value out of the dynamic object into the runtime process image.

BFD_RELOC_MI CROBLAZE_64_TLS

Unused Reloc

BFD_RELOC_MI CROBLAZE_64_TLSGD

This is a 64 bit reloc that stores the 32 bit GOT relative value of the GOT TLS GD info entry in two words (with an imm instruction). The relocation is GOT o set.

BFD_RELOC_MI CROBLAZE_64_TLSLD

This is a 64 bit reloc that stores the 32 bit GOT relative value of the GOT TLS LD info entry in two words (with an imm instruction). The relocation is GOT o set.

BFD RELOC MICROBLAZE 32 TLSDTPMOD

This is a 32 bit reloc that stores the Module ID to GOT(n).

BFD_RELOC_MI CROBLAZE_32_TLSDTPREL

This is a 32 bit reloc that stores TLS o set to GOT(n+1).

BFD RELOC MICROBLAZE 64 TLSDTPREL

This is a 32 bit reloc for storing TLS o set to two words (uses imm instruction)

BFD RELOC MICROBLAZE 64 TLSGOTTPREL

This is a 64 bit reloc that stores 32-bit thread pointer relative o set to two words (uses imm instruction).

BFD RELOC MICROBLAZE 64 TLSTPREL

This is a 64 bit reloc that stores 32-bit thread pointer relative o set to two words (uses imm instruction).

BFD_RELOC_AARCH64_RELOC_START

AArch64 pseudo relocation code to mark the start of the AArch64 relocation enumerators. N.B. the order of the enumerators is important as several tables in the AArch64 bfd backend are indexed by these enumerators; make sure they are all synced.

BFD RELOC AARCH64 NULL

Deprecated AArch64 null relocation code.

BFD_RELOC_AARCH64_NONE

AArch64 null relocation code.

BFD_RELOC_AARCH64_64

BFD RELOC AARCH64 32

BFD_RELOC_AARCH64_16

Basic absolute relocations of N bits. These are equivalent to BFD_RELOC_N and they were added to assist the indexing of the howto table.

BFD RELOC AARCH64 64 PCREL

BFD RELOC AARCH64 32 PCREL

BFD_RELOC_AARCH64_16_PCREL

PC-relative relocations. These are equivalent to BFD_RELOC_N_PCREL and they were added to assist the indexing of the howto table.

BFD RELOC AARCH64 MOVW GO

AArch64 MOV[NZK] instruction with most signi cant bits 0 to 15 of an unsigned address/value.

BFD_RELOC_AARCH64_MOVW_GO_NC

AArch64 MOV[NZK] instruction with less signicant bits 0 to 15 of an address/value. No over ow checking.

BFD RELOC AARCH64 MOVW G1

AArch64 MOV[NZK] instruction with most signil cant bits 16 to 31 of an unsigned address/value.

BFD RELOC AARCH64 MOVW G1 NC

AArch64 MOV[NZK] instruction with less signicant bits 16 to 31 of an address/value. No over ow checking.

BFD RELOC AARCH64 MOVW G2

AArch64 MOV[NZK] instruction with most signi cant bits 32 to 47 of an unsigned address/value.

BFD_RELOC_AARCH64_MOVW_G2_NC

AArch64 MOV[NZK] instruction with less signicant bits 32 to 47 of an address/value. No over ow checking.

BFD RELOC AARCH64 MOVW G3

AArch64 MOV[NZK] instruction with most sign cant bits 48 to 64 of a signed or unsigned address/value.

BFD_RELOC_AARCH64_MOVW_GO_S

AArch64 MOV[NZ] instruction with most signi cant bits 0 to 15 of a signed value. Changes instruction to MOVZ or MOVN depending on the value's sign.

BFD RELOC AARCH64 MOVW G1 S

AArch64 MOV[NZ] instruction with most signicant bits 16 to 31 of a signed value. Changes instruction to MOVZ or MOVN depending on the value's sign.

BFD RELOC AARCH64 MOVW G2 S

AArch64 MOV[NZ] instruction with most signicant bits 32 to 47 of a signed value. Changes instruction to MOVZ or MOVN depending on the value's sign.

BFD RELOC AARCH64 LD L019 PCREL

AArch64 Load Literal instruction, holding a 19 bit pc-relative word o set. The lowest two bits must be zero and are not stored in the instruction, giving a 21 bit signed byte o set.

BFD_RELOC_AARCH64_ADR_L021_PCREL

AArch64 ADR instruction, holding a simple 21 bit pc-relative byte o set.

BFD_RELOC_AARCH64_ADR_HI 21_PCREL

AArch64 ADRP instruction, with bits 12 to 32 of a pc-relative page o set, giving a 4KB aligned page base address.

BFD_RELOC_AARCH64_ADR_HI 21_NC_PCREL

AArch64 ADRP instruction, with bits 12 to 32 of a pc-relative page o set, giving a 4KB aligned page base address, but with no over ow checking.

BFD RELOC AARCH64 ADD L012

AArch64 ADD immediate instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD_RELOC_AARCH64_LDST8_L012

AArch64 8-bit load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD RELOC AARCH64 TSTBR14

AArch64 14 bit pc-relative test bit and branch. The lowest two bits must be zero and are not stored in the instruction, giving a 16 bit signed byte o set.

BFD RELOC AARCH64 BRANCH19

AArch64 19 bit pc-relative conditional branch and compare & branch. The lowest two bits must be zero and are not stored in the instruction, giving a 21 bit signed byte o set.

BFD RELOC AARCH64 JUMP26

AArch64 26 bit pc-relative unconditional branch. The lowest two bits must be zero and are not stored in the instruction, giving a 28 bit signed byte o set.

BFD_RELOC_AARCH64_CALL26

AArch64 26 bit pc-relative unconditional branch and link. The lowest two bits must be zero and are not stored in the instruction, giving a 28 bit signed byte o set.

BFD RELOC AARCH64 LDST16 L012

AArch64 16-bit load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD RELOC AARCH64 LDST32 L012

AArch64 32-bit load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD RELOC AARCH64 LDST64 L012

AArch64 64-bit load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD RELOC AARCH64 LDST128 L012

AArch64 128-bit load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD RELOC AARCH64 GOT LD PREL19

AArch64 Load Literal instruction, holding a 19 bit PC relative word o set of the global o set table entry for a symbol. The lowest two bits must be zero and are not stored in the instruction, giving a 21 bit signed byte o set. This relocation type requires signed over ow checking.

BFD_RELOC_AARCH64_ADR_GOT_PAGE

Get to the page base of the global o set table entry for a symbol as part of an ADRP instruction using a 21 bit PC relative value. Used in conjunction with BFD_RELOC_AARCH64_LD64_GOT_LO12_NC.

BFD RELOC AARCH64 LD64 GOT LO12 NC

Unsigned 12 bit byte o set for 64 bit load/store from the page of the GOT entry for this symbol. Used in conjunction with BFD_RELOC_AARCH64_ADR_GOT_PAGE. Valid in LP64 ABI only.

BFD_RELOC_AARCH64_LD32_GOT_LO12_NC

Unsigned 12 bit byte o set for 32 bit load/store from the page of the GOT entry for this symbol. Used in conjunction with BFD_RELOC_AARCH64_ADR_GOT_PAGE. Valid in ILP32 ABI only.

BFD_RELOC_AARCH64_MOVW_GOTOFF_GO_NC

Unsigned 16 bit byte o set for 64 bit load/store from the GOT entry for this symbol. Valid in LP64 ABI only.

BFD_RELOC_AARCH64_MOVW_GOTOFF_G1

Unsigned 16 bit byte higher o set for 64 bit load/store from the GOT entry for this symbol. Valid in LP64 ABI only.

BFD_RELOC_AARCH64_LD64_GOT0FF_L015

Unsigned 15 bit byte o set for 64 bit load/store from the page of the GOT entry for this symbol. Valid in LP64 ABI only.

BFD RELOC AARCH64 LD32 GOTPAGE LO14

Scaled 14 bit byte o set to the page base of the global o set table.

BFD_RELOC_AARCH64_LD64_GOTPAGE_L015

Scaled 15 bit byte o set to the page base of the global o set table.

BFD_RELOC_AARCH64_TLSGD_ADR_PAGE21

Get to the page base of the global o set table entry for a symbols tls_index structure as part of an adrp instruction using a 21 bit PC relative value. Used in conjunction with BFD_RELOC_AARCH64_TLSGD_ADD_LO12_NC.

BFD_RELOC_AARCH64_TLSGD_ADR_PREL21

AArch64 TLS General Dynamic

BFD_RELOC_AARCH64_TLSGD_ADD_L012_NC

Unsigned 12 bit byte o set to global o set table entry for a symbols tls_index structure. Used in conjunction with BFD_RELOC_AARCH64_TLSGD_ADR_PAGE21.

BFD_RELOC_AARCH64_TLSGD_MOVW_GO_NC

AArch64 TLS General Dynamic relocation.

BFD RELOC AARCH64 TLSGD MOVW G1

AArch64 TLS General Dynamic relocation.

- BFD_RELOC_AARCH64_TLSI E_ADR_GOTTPREL_PAGE21 AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSI E_LD64_GOTTPREL_L012_NC AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSI E_LD32_GOTTPREL_L012_NC AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSI E_LD_GOTTPREL_PREL19 AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSI E_MOVW_GOTTPREL_GO_NC AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSI E_MOVW_GOTTPREL_G1 AArch64 TLS INITIAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLD_ADD_DTPREL_HI 12 bit[23:12] of byte o set to module TLS base address.
- BFD_RELOC_AARCH64_TLSLD_ADD_DTPREL_L012
 Unsigned 12 bit byte o set to module TLS base address.
- BFD_RELOC_AARCH64_TLSLD_ADD_DTPREL_L012_NC

 No over ow check version of BFD_RELOC_AARCH64_TLSLD_ADD_DTPREL_L012.
- BFD_RELOC_AARCH64_TLSLD_ADD_L012_NC

 Unsigned 12 bit byte o set to global o set table entry for a symbols tls_index structure. Used in conjunction with BFD_RELOC_AARCH64_TLSLD_ADR_PAGE21.
- BFD_RELOC_AARCH64_TLSLD_ADR_PAGE21

 GOT entry page address for AArch64 TLS Local Dynamic, used with ADRP instruction.
- BFD_RELOC_AARCH64_TLSLD_ADR_PREL21

 GOT entry address for AArch64 TLS Local Dynamic, used with ADR instruction.
- BFD_RELOC_AARCH64_TLSLD_LDST16_DTPREL_L012 bit[11:1] of byte o set to module TLS base address, encoded in ldst instructions.
- BFD_RELOC_AARCH64_TLSLD_LDST16_DTPREL_L012_NC Similar as BFD_RELOC_AARCH64_TLSLD_LDST16_DTPREL_L012, but no overow check.
- BFD_RELOC_AARCH64_TLSLD_LDST32_DTPREL_L012 bit[11:2] of byte o set to module TLS base address, encoded in ldst instructions.
- BFD_RELOC_AARCH64_TLSLD_LDST32_DTPREL_L012_NC Similar as BFD_RELOC_AARCH64_TLSLD_LDST32_DTPREL_L012, but no overow check.

- BFD_RELOC_AARCH64_TLSLD_LDST64_DTPREL_L012 bit[11:3] of byte o set to module TLS base address, encoded in ldst instructions.
- BFD_RELOC_AARCH64_TLSLD_LDST64_DTPREL_L012_NC Similar as BFD_RELOC_AARCH64_TLSLD_LDST64_DTPREL_L012, but no overow check.
- BFD_RELOC_AARCH64_TLSLD_LDST8_DTPREL_L012 bit[11:0] of byte o set to module TLS base address, encoded in ldst instructions.
- BFD_RELOC_AARCH64_TLSLD_LDST8_DTPREL_L012_NC Similar as BFD_RELOC_AARCH64_TLSLD_LDST8_DTPREL_L012, but no overow check.
- BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_GO bit[15:0] of byte o set to module TLS base address.
- BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_GO_NC

 No over ow check version of BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_GO
- BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_G1 bit[31:16] of byte o set to module TLS base address.
- BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_G1_NC

 No over ow check version of BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_G1
- BFD_RELOC_AARCH64_TLSLD_MOVW_DTPREL_G2 bit[47:32] of byte o set to module TLS base address.
- BFD_RELOC_AARCH64_TLSLE_MOVW_TPREL_G2 AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_MOVW_TPREL_G1 AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_MOVW_TPREL_G1_NC AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_MOVW_TPREL_GO AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_MOVW_TPREL_GO_NC AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_ADD_TPREL_L012 AArch64 TLS LOCAL EXEC relocation.
- BFD_RELOC_AARCH64_TLSLE_ADD_TPREL_L012_NC AArch64 TLS LOCAL EXEC relocation.

- BFD_RELOC_AARCH64_TLSDESC_LD_PREL19 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_ADR_PREL21 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_ADR_PAGE21 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_LD64_L012
 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_LD32_L012_NC AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_ADD_L012 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_OFF_G1 AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_OFF_GO_NC AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_LDR AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_ADD AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_TLSDESC_CALL AArch64 TLS DESC relocation.
- BFD_RELOC_AARCH64_COPY
 AArch64 TLS relocation.
- BFD_RELOC_AARCH64_GL0B_DAT AArch64 TLS relocation.
- BFD_RELOC_AARCH64_JUMP_SLOT AArch64 TLS relocation.
- BFD_RELOC_AARCH64_RELATI VE AArch64 TLS relocation.
- BFD_RELOC_AARCH64_TLS_DTPMOD AArch64 TLS relocation.
- BFD_RELOC_AARCH64_TLS_DTPREL AArch64 TLS relocation.
- BFD_RELOC_AARCH64_TLS_TPREL AArch64 TLS relocation.

BFD_RELOC_AARCH64_TLSDESC AArch64 TLS relocation.

BFD RELOC AARCH64 IRELATIVE

AArch64 support for STT_GNU_IFUNC.

BFD RELOC AARCH64 RELOC END

AArch64 pseudo relocation code to mark the end of the AArch64 relocation enumerators that have direct mapping to ELF reloc codes. There are a few more enumerators after this one; those are mainly used by the AArch64 assembler for the internal xup or to select one of the above enumerators.

BFD_RELOC_AARCH64_GAS_INTERNAL_FIXUP

AArch64 pseudo relocation code to be used internally by the AArch64 assembler and not (currently) written to any object les.

BFD RELOC AARCH64 LDST L012

AArch64 unspeci ed load/store instruction, holding bits 0 to 11 of the address. Used in conjunction with BFD_RELOC_AARCH64_ADR_HI21_PCREL.

BFD_RELOC_AARCH64_TLSLD_LDST_DTPREL_L012

AArch64 pseudo relocation code for TLS local dynamic mode. It's to be used internally by the AArch64 assembler and not (currently) written to any object les.

BFD RELOC AARCH64 TLSLD LDST DTPREL L012 NC

Similar as BFD_RELOC_AARCH64_TLSLD_LDST_DTPREL_LO12, but no overow check.

BFD RELOC AARCH64 LD GOT LO12 NC

AArch64 pseudo relocation code to be used internally by the AArch64 assembler and not (currently) written to any object les.

BFD_RELOC_AARCH64_TLSI E_LD_GOTTPREL_L012_NC

AArch64 pseudo relocation code to be used internally by the AArch64 assembler and not (currently) written to any object les.

BFD_RELOC_AARCH64_TLSDESC_LD_L012_NC

AArch64 pseudo relocation code to be used internally by the AArch64 assembler and not (currently) written to any object les.

     typedef enum bfd reloc code real bfd reloc code real type;
2.10.2.2 bfd_reloc_type_lookup
Synopsis
     reloc_howto_type *bfd_reloc_type_lookup
        (bfd *abfd, bfd reloc code real type code);
     rel oc_howto_type *bfd_rel oc_name_l ookup
```

Description

Return a pointer to a howto structure which, when invoked, will perform the relocation code on data from the architecture noted.

(bfd *abfd, const char *reloc_name);

2.10.2.3 bfd_default_reloc_type_lookup

Synopsis

```
rel oc_howto_type *bfd_defaul t_rel oc_type_l ookup
  (bfd *abfd, bfd_rel oc_code_real_type code);
```

Description

Provides a default relocation lookup routine for any architecture.

2.10.2.4 bfd_get_reloc_code_name

Synopsis

```
const char *bfd get reloc code name (bfd reloc code real type code);
```

Description

Provides a printable name for the supplied relocation code. Useful mainly for printing error messages.

2.10.2.5 bfd_generic_relax_section

Synopsis

```
bfd_boolean bfd_generic_relax_section
  (bfd *abfd,
    asection *section,
    struct bfd_link_info *,
    bfd_boolean *);
```

Description

Provides default handling for relaxing for back ends which don't do relaxing.

2.10.2.6 bfd_generic_gc_sections

Synopsis

```
bfd_boolean bfd_generic_gc_sections
  (bfd *, struct bfd_link_info *);
```

Description

Provides default handling for relaxing for back ends which don't do section gc { i.e., does nothing.

2.10.2.7 bfd_generic_lookup_section_flags

Synopsis

```
bfd_boolean bfd_generic_lookup_section_flags
  (struct bfd_link_info *, struct flag_info *, asection *);
```

Description

Provides default handling for section ags lookup { i.e., does nothing. Returns FALSE if the section should be omitted, otherwise TRUE.

2.10.2.8 bfd_generic_merge_sections

Synopsis

```
bfd_boolean bfd_generic_merge_sections
  (bfd *, struct bfd_link_info *);
```

Description

Provides default handling for SEC_MERGE section merging for back ends which don't have SEC_MERGE support { i.e., does nothing.

2.10.2.9 bfd_generic_get_relocated_section_contents

Synopsis

```
bfd_byte *bfd_generic_get_relocated_section_contents
  (bfd *abfd,
    struct bfd_link_info *link_info,
    struct bfd_link_order *link_order,
    bfd_byte *data,
    bfd_boolean relocatable,
    asymbol **symbols);
```

Description

Provides default handling of relocation e ort for back ends which can't be bothered to do it e ciently.

2.10.2.10 _bfd_generic_set_reloc

Synopsis

```
void _bfd_generic_set_reloc
  (bfd *abfd,
    sec_ptr section,
    arelent **relptr,
    unsigned int count);
```

Description

Installs a new set of internal relocations in SECTION.

2.10.2.11 _bfd_unrecognized_reloc

Synopsis

```
bfd_bool ean _bfd_unrecogni zed_rel oc
  (bfd * abfd,
    sec_ptr section,
    unsigned int r_type);
```

Description

Reports an unrecognized reloc. Written as a function in order to reduce code duplication. Returns FALSE so that it can be called from a return statement.

2.11 Core files

2.11.1 Core file functions

Description

These are functions pertaining to core les.

2.11.1.1 bfd_core_file_failing_command

Synopsis

```
const char *bfd_core_file_failing_command (bfd *abfd);
```

Description

Return a read-only string explaining which program was running when it failed and produced the core le abfd.

2.11.1.2 bfd_core_file_failing_signal

Synopsis

```
int bfd_core_file_failing_signal (bfd *abfd);
```

Description

Returns the signal number which caused the core dump which generated the le the BFD *abfd* is attached to.

2.11.1.3 bfd_core_file_pid

Synopsis

```
int bfd_core_file_pid (bfd *abfd);
```

Description

Returns the PID of the process the core dump the BFD *abfd* is attached to was generated from.

2.11.1.4 core_file_matches_executable_p

Synopsis

```
bfd_boolean core_file_matches_executable_p
  (bfd *core_bfd, bfd *exec_bfd);
```

Description

Return TRUE if the core le attached to $core_bfd$ was generated by a run of the executable le attached to $exec_bfd$, FALSE otherwise.

2.11.1.5 generic_core_file_matches_executable_p

Synopsis

```
bfd_bool ean generic_core_file_matches_executable_p
   (bfd *core_bfd, bfd *exec_bfd);
```

Description

Return TRUE if the core le attached to $core_bfd$ was generated by a run of the executable le attached to $exec_bfd$. The match is based on executable basenames only.

Note: When not able to determine the core le failing command or the executable name, we still return TRUE even though we're not sure that core le and executable match. This is to avoid generating a false warning in situations where we really don't know whether they match or not.

2.12 Targets

Description

Each port of BFD to a di erent machine requires the creation of a target back end. All the back end provides to the root part of BFD is a structure containing pointers to functions which perform certain low level operations on les. BFD translates the applications's requests through a pointer into calls to the back end routines.

When a le is opened with bfd_openr, its format and target are unknown. BFD uses various mechanisms to determine how to interpret the le. The operations performed are:

- Create a BFD by calling the internal routine _bfd_new_bfd, then call bfd_find_ target with the target string supplied to bfd_openr and the new BFD pointer.
- If a null target string was provided to bfd_find_target, look up the environment variable GNUTARGET and use that as the target string.
- If the target string is still NULL, or the target string is default, then use the rst item in the target vector as the target type, and set target_defaulted in the BFD to cause bfd_check_format to loop through all the targets. See Section 2.12.1 [bfd_target], page 141. See Section 2.9 [Formats], page 53.
- Otherwise, inspect the elements in the target vector one by one, until a match on target name is found. When found, use it.
- Otherwise return the error bfd_error_i nval i d_target to bfd_openr.
- bfd_openr attempts to open the le using bfd_open_file, and returns the BFD.

Once the BFD has been opened and the target selected, the le format may be determined. This is done by calling bfd_check_format on the BFD with a suggested format. If target_defaul ted has been set, each possible target type is tried to see if it recognizes the specified format. bfd_check_format returns TRUE when the caller guesses right.

2.12.1 bfd_target

Description

This structure contains everything that BFD knows about a target. It includes things like its byte order, name, and which routines to call to do various operations.

Every BFD points to a target structure with its xvec member.

The macros below are used to dispatch to functions through the bfd_target vector. They are used in a number of macros further down in `bfd. h', and are also used when calling various routines by hand inside the BFD implementation. The *arglist* argument must be parenthesized; it contains all the arguments to the called function.

They make the documentation (more) unpleasant to read, so if someone wants to x this and not break the above, please do.

```
#define BFD_SEND(bfd, message, arglist) \
    ((*((bfd)->xvec->message)) arglist)

#ifdef DEBUG_BFD_SEND
#undef BFD_SEND
#define BFD_SEND(bfd, message, arglist) \
    (((bfd) && (bfd)->xvec && (bfd)->xvec->message) ? \
```

```
((*((bfd)->xvec->message)) arglist) : \
    (bfd_assert (__FILE__, __LINE__), NULL))
#endif
For operations which index on the BFD format:
    #define BFD_SEND_FMT(bfd, message, arglist) \
    (((bfd)->xvec->message[(int) ((bfd)->format)]) arglist)

#ifdef DEBUG_BFD_SEND
#undef BFD_SEND_FMT
#define BFD_SEND_FMT(bfd, message, arglist) \
    (((bfd) && (bfd)->xvec && (bfd)->xvec->message) ? \
    (((bfd)->xvec->message[(int) ((bfd)->format)]) arglist) : \
    (bfd_assert (__FILE__, __LINE__), NULL))
#endif
```

This is the structure which de nes the type of BFD this is. The xvec member of the struct bfd itself points here. Each module that implements access to a di erent target under BFD, de nes one of these.

FIXME, these names should be rationalised with the names of the entry points which call them. Too bad we can't have one macro to de ne them both!

```

```

A pointer to an alternative bfd_target in case the current one is not satisfactory. This can happen when the target cpu supports both big and little endian code, and target chosen by the linker has the wrong endianness. The function open_output() in Id/Idlang.c uses this eld to nd an alternative output format that is suitable.

```
/* Opposite endian version of this target. */
const struct bfd_target *alternative_target;

/* Data for use by back-end routines, which isn't
    generic enough to belong in this structure. */
const void *backend_data;
} bfd_target;
```

2.12.1.1 bfd_set_default_target

Synopsis

bfd_boolean bfd_set_default_target (const char *name);

Description

Set the default target vector to use when recognizing a BFD. This takes the name of the target, which may be a BFD target name or a con guration triplet.

2.12.1.2 bfd_find_target

Synopsis

```
const bfd target *bfd find target (const char *target name, bfd *abfd);
```

Description

Return a pointer to the transfer vector for the object target named $target_name$. If $target_name$ is NULL, choose the one in the environment variable GNUTARGET; if that is null or

not de ned, then choose the rst entry in the target list. Passing in the string "default" or setting the environment variable to "default" will cause the rst entry in the target list to be returned, and "target_defaulted" will be set in the BFD if abfd isn't NULL. This causes bfd_check_format to loop over all the targets to nd the one that matches the le being read.

2.12.1.3 bfd_get_target_info

Synopsis

```
const bfd_target *bfd_get_target_info (const char *target_name,
    bfd *abfd,
    bfd_bool ean *is_bi gendi an,
    int *underscori ng,
    const char **def target arch);
```

Description

Return a pointer to the transfer vector for the object target named $target_name$. If $target_name$ is NULL, choose the one in the environment variable GNUTARGET; if that is null or not de ned, then choose the rst entry in the target list. Passing in the string "default" or setting the environment variable to "default" will cause the rst entry in the target list to be returned, and "target_defaulted" will be set in the BFD if abfd isn't NULL. This causes bfd_check_format to loop over all the targets to nd the one that matches the le being read. If $is_bigendian$ is not NULL, then set this value to target's endian mode. True for big-endian, FALSE for little-endian or for invalid target. If underscoring is not NULL, then set this value to target's underscoring mode. Zero for none-underscoring, -1 for invalid target, else the value of target vector's symbol underscoring. If def_target_arch is not NULL, then set it to the architecture string speci ed by the target_name.

2.12.1.4 bfd_target_list

Synopsis

```
const char ** bfd_target_list (void);
```

Description

Return a freshly malloced NULL-terminated vector of the names of all the valid BFD targets. Do not modify the names.

2.12.1.5 bfd_iterate_over_targets

Synopsis

```
const bfd_target *bfd_iterate_over_targets
  (int (*func) (const bfd_target *, void *),
   void *data);
```

Description

Call func for each target in the list of BFD target vectors, passing data to func. Stop iterating if func returns a non-zero result, and return that target vector. Return NULL if func always returns zero.

2.12.1.6 bfd_flavour_name

Synopsis

```
const char *bfd_flavour_name (enum bfd_flavour flavour);
```

Description

Return the string form of flavour.

2.13 Architectures

BFD keeps one atom in a BFD describing the architecture of the data attached to the BFD: a pointer to a bfd_arch_i nfo_type.

Pointers to structures can be requested independently of a BFD so that an architecture's information can be interrogated without access to an open BFD.

The architecture information is provided by each architecture package. The set of default architectures is selected by the macro SELECT_ARCHITECTURES. This is normally set up in the `config/target.mt' le of your choice. If the name is not de ned, then all the architectures supported are included.

When BFD starts up, all the architectures are called with an initialize method. It is up to the architecture back end to insert as many items into the list of architectures as it wants to; generally this would be one for each machine and one for the default case (an item with a machine eld of 0).

BFD's idea of an architecture is implemented in `archures. c'.

2.13.1 bfd_architecture

Description

This enum gives the object le's CPU architecture, in a global sense | i.e., what processor family does it belong to? Another eld indicates which processor within the family is in use. The machine gives a number which distinguishes di erent versions of the architecture, containing, for example, 2 and 3 for Intel i960 KA and i960 KB, and 68020 and 68030 for Motorola 68020 and 68030.

```
enum bfd_architecture
 bfd arch unknown,
                      /* File arch not known.
                      /* Arch known, not one of these. */
 bfd_arch_obscure,
 bfd_arch_m68k,
                      /* Motorola 68xxx.
                                          */

2.13.2 bfd_arch_info

Description

This structure contains information on architectures for use within BFD.

```
typedef struct bfd_arch_info
{
  int bits_per_word;
  int bits_per_address;
  int bits_per_byte;
  enum bfd_architecture arch;
  unsigned long mach;
  const char *arch_name;
  const char *printable_name;
  unsigned int section_align_power;
```

2.13.2.1 bfd_printable_name

Synopsis

const char *bfd_printable_name (bfd *abfd);

Description

Return a printable string representing the architecture and machine from the pointer to the architecture info structure.

2.13.2.2 bfd_scan_arch

Synopsis

```
const bfd_arch_info_type *bfd_scan_arch (const char *string);
```

Description

Figure out if BFD supports any cpu which could be described with the name string. Return a pointer to an arch_i nfo structure if a machine is found, otherwise NULL.

2.13.2.3 bfd_arch_list

Synopsis

```
const char **bfd_arch_list (void);
```

Description

Return a freshly malloced NULL-terminated vector of the names of all the valid BFD architectures. Do not modify the names.

2.13.2.4 bfd_arch_get_compatible

Synopsis

```
const bfd_arch_info_type *bfd_arch_get_compatible
  (const bfd *abfd, const bfd *bbfd, bfd_boolean accept_unknowns);
```

Description

Determine whether two BFDs' architectures and machine types are compatible. Calculates the lowest common denominator between the two architectures and machine types implied by the BFDs and returns a pointer to an arch_i nfo structure describing the compatible machine.

2.13.2.5 bfd_default_arch_struct

Description

The bfd_defaul t_arch_struct is an item of bfd_arch_i nfo_type which has been initialized to a fairly generic state. A BFD starts life by pointing to this structure, until the correct back end has determined the real architecture of the le.

extern const bfd_arch_info_type bfd_default_arch_struct;

2.13.2.6 bfd_set_arch_info

Synopsis

```
void bfd_set_arch_info (bfd *abfd, const bfd_arch_info_type *arg);
```

Description

Set the architecture info of abfd to arg.

2.13.2.7 bfd_default_set_arch_mach

Synopsis

```
bfd_boolean bfd_default_set_arch_mach
  (bfd *abfd, enum bfd_architecture arch, unsigned long mach);
```

Description

Set the architecture and machine type in BFD *abfd* to *arch* and *mach*. Find the correct pointer to a structure and insert it into the arch_i nfo pointer.

2.13.2.8 bfd_get_arch

Synopsis

```
enum bfd_archi tecture bfd_get_arch (bfd *abfd);
```

Description

Return the enumerated type which describes the BFD *abfd*'s architecture.

2.13.2.9 bfd_get_mach

Synopsis

```
unsigned long bfd_get_mach (bfd *abfd);
```

Description

Return the long type which describes the BFD abfd's machine.

2.13.2.10 bfd_arch_bits_per_byte

Synopsis

```
unsigned int bfd_arch_bits_per_byte (bfd *abfd);
```

Description

Return the number of bits in one of the BFD *abfd*'s architecture's bytes.

2.13.2.11 bfd_arch_bits_per_address

Synopsis

```
unsigned int bfd_arch_bits_per_address (bfd *abfd);
```

Description

Return the number of bits in one of the BFD *abfd*'s architecture's addresses.

2.13.2.12 bfd_default_compatible

Synopsis

```
const bfd_arch_info_type *bfd_default_compatible
  (const bfd_arch_info_type *a, const bfd_arch_info_type *b);
```

Description

The default function for testing for compatibility.

2.13.2.13 bfd_default_scan

Synopsis

```
bfd_boolean bfd_default_scan
  (const struct bfd_arch_info *info, const char *string);
```

Description

The default function for working out whether this is an architecture hit and a machine hit.

2.13.2.14 bfd_get_arch_info

Synopsis

```
const bfd_arch_info_type *bfd_get_arch_info (bfd *abfd);
```

Description

Return the architecture info struct in abfd.

2.13.2.15 bfd_lookup_arch

Synopsis

```
const bfd_arch_info_type *bfd_lookup_arch
  (enum bfd_architecture arch, unsigned long machine);
```

Description

Look for the architecture info structure which matches the arguments arch and machine. A machine of 0 matches the machine/architecture structure which marks itself as the default.

2.13.2.16 bfd_printable_arch_mach

Synopsis

```
const char *bfd_printable_arch_mach
  (enum bfd_architecture arch, unsigned long machine);
```

Description

Return a printable string representing the architecture and machine type.

This routine is depreciated.

2.13.2.17 bfd_octets_per_byte

Synopsis

unsigned int bfd_octets_per_byte (bfd *abfd);

Description

Return the number of octets (8-bit quantities) per target byte (minimum addressable unit). In most cases, this will be one, but some DSP targets have 16, 32, or even 48 bits per byte.

2.13.2.18 bfd_arch_mach_octets_per_byte

Synopsis

```
unsigned int bfd_arch_mach_octets_per_byte
  (enum bfd_architecture arch, unsigned long machine);
```

Description

See bfd_octets_per_byte.

This routine is provided for those cases where a bfd * is not available

2.13.2.19 bfd_arch_default_fill

Synopsis

```
void *bfd_arch_default_fill (bfd_size_type count,
    bfd_bool ean is_bigendian,
    bfd_bool ean code);
```

Description

Allocate via bfd_malloc and return a II bu er of size COUNT. If IS_BIGENDIAN is TRUE, the order of bytes is big endian. If CODE is TRUE, the bu er contains code.

/* Set to N to open the next N BFDs using an alternate id space. */
extern unsigned int bfd_use_reserved_id;

2.14 Opening and closing BFDs

2.14.1 Functions for opening and closing

2.14.1.1 bfd_fopen

Synopsis

Description

Open the le *filename* with the target *target*. Return a pointer to the created BFD. If *fd* is not -1, then fdopen is used to open the le; otherwise, fopen is used. *mode* is passed directly to fopen or fdopen.

Calls bfd_fi nd_target, so *target* is interpreted as by that function.

The new BFD is marked as cacheable i fd is -1.

If NULL is returned then an error has occured. Possible errors are bfd_error_no_memory, bfd_error_i nvalid_target or system_call error.

On error, fd is always closed.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.2 bfd_openr

Synopsis

bfd *bfd_openr (const char *filename, const char *target);

Description

Open the le *filename* (using fopen) with the target *target*. Return a pointer to the created BFD.

Calls bfd_fi nd_target, so *target* is interpreted as by that function.

If NULL is returned then an error has occured. Possible errors are bfd_error_no_memory, bfd_error_i nvalid_target or system_call error.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.3 bfd_fdopenr

Synopsis

bfd *bfd_fdopenr (const char *filename, const char *target, int fd);

Description

bfd_fdopenr is to bfd_fopenr much like fdopen is to fopen. It opens a BFD on a le already described by the fd supplied.

When the le is later bfd_cl osed, the le descriptor will be closed. If the caller desires that this le descriptor be cached by BFD (opened as needed, closed as needed to free descriptors for other opens), with the supplied fd used as an initial le descriptor (but subject to closure at any time), call bfd_set_cacheable(bfd, 1) on the returned BFD. The default is to assume no caching; the le descriptor will remain open until bfd_cl ose, and will not be a ected by BFD operations on other les.

Possible errors are bfd_error_no_memory, bfd_error_invalid_target and bfd_error_system_call.

On error, fd is closed.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.4 bfd_openstreamr

Synopsis

```
bfd *bfd_openstreamr (const char * filename, const char * target,
    void * stream);
```

Description

Open a BFD for read access on an existing stdio stream. When the BFD is passed to bfd close, the stream will be closed.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_qet_ lename() macro.

2.14.1.5 bfd_openr_iovec

Synopsis

```
bfd *bfd_openr_iovec (const char *filename, const char *target,
    void *(*open_func) (struct bfd *nbfd,
    void *open_closure),
    void *open_closure,
    file_ptr (*pread_func) (struct bfd *nbfd,
    void *stream,
    void *buf,
    file_ptr nbytes,
    file_ptr offset),
    int (*close_func) (struct bfd *nbfd,
    void *stream),
    int (*stat_func) (struct bfd *abfd,
    void *stream,
    struct stat *sb));
```

Description

Create and return a BFD backed by a read-only *stream*. The *stream* is created using *open_func*, accessed using *pread_func* and destroyed using *close_func*.

Calls bfd_find_target, so *target* is interpreted as by that function.

Calls $open_func$ (which can call bfd_zalloc and bfd_get_filename) to obtain the readonly stream backing the BFD. $open_func$ either succeeds returning the non-NULL stream, or fails returning NULL (setting bfd_error).

Calls $pread_func$ to request nbytes of data from stream starting at offset (e.g., via a call to bfd_read). $pread_func$ either succeeds returning the number of bytes read (which can be less than nbytes when end-of- le), or fails returning -1 (setting bfd_error).

Calls *close_func* when the BFD is later closed using bfd_close. *close_func* either succeeds returning 0, or fails returning -1 (setting bfd_error).

Calls $stat_func$ to II in a stat structure for bfd_stat, bfd_get_size, and bfd_get_mtime calls. $stat_func$ returns 0 on success, or returns -1 on failure (setting bfd_error).

If bfd_openr_i ovec returns NULL then an error has occurred. Possible errors are bfd_error_no_memory, bfd_error_i nvalid_target and bfd_error_system_call.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.6 bfd_openw

Synopsis

```
bfd *bfd_openw (const char *filename, const char *target);
```

Description

Create a BFD, associated with le *filename*, using the le format target, and return a pointer to it.

Possible errors are bfd_error_system_call, bfd_error_no_memory, bfd_error_i nvalid_target.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.7 bfd_close

Synopsis

bfd_bool ean bfd_close (bfd *abfd);

Description

Close a BFD. If the BFD was open for writing, then pending operations are completed and the le written out and closed. If the created le is executable, then chmod is called to mark it as such.

All memory attached to the BFD is released.

The le descriptor associated with the BFD is closed (even if it was passed in to BFD by bfd_fdopenr).

Returns

TRUE is returned if all is ok, otherwise FALSE.

2.14.1.8 bfd_close_all_done

Synopsis

bfd_boolean bfd_close_all_done (bfd *);

Description

Close a BFD. Di ers from bfd_close since it does not complete any pending operations. This routine would be used if the application had just used BFD for swapping and didn't want to use any of the writing code.

If the created le is executable, then chmod is called to mark it as such.

All memory attached to the BFD is released.

Returns

TRUE is returned if all is ok, otherwise FALSE.

2.14.1.9 bfd_create

Synopsis

bfd *bfd_create (const char *filename, bfd *templ);

Description

Create a new BFD in the manner of bfd_openw, but without opening a le. The new BFD takes the target from the target used by templ. The format is always set to bfd_obj ect.

A copy of the *filename* argument is stored in the newly created BFD. It can be accessed via the bfd_get_ lename() macro.

2.14.1.10 bfd_make_writable

Synopsis

bfd_boolean bfd_make_writable (bfd *abfd);

Description

Takes a BFD as created by bfd_create and converts it into one like as returned by bfd_openw. It does this by converting the BFD to BFD_IN_MEMORY. It's assumed that you will call bfd_make_readable on this bfd later.

Returns

TRUE is returned if all is ok, otherwise FALSE.

2.14.1.11 bfd_make_readable

Synopsis

bfd_boolean bfd_make_readable (bfd *abfd);

Description

Takes a BFD as created by bfd_create and bfd_make_writable and converts it into one like as returned by bfd_openr. It does this by writing the contents out to the memory bu er, then reversing the direction.

Returns

TRUE is returned if all is ok, otherwise FALSE.

2.14.1.12 bfd alloc

Synopsis

void *bfd_alloc (bfd *abfd, bfd_size_type wanted);

Description

Allocate a block of wanted bytes of memory attached to abfd and return a pointer to it.

2.14.1.13 bfd_alloc2

Synopsis

void *bfd_alloc2 (bfd *abfd, bfd_size_type nmemb, bfd_size_type size);

Description

Allocate a block of *nmemb* elements of *size* bytes each of memory attached to abfd and return a pointer to it.

2.14.1.14 bfd_zalloc

Synopsis

void *bfd_zalloc (bfd *abfd, bfd_size_type wanted);

Description

Allocate a block of wanted bytes of zeroed memory attached to abfd and return a pointer to it.

2.14.1.15 bfd_zalloc2

Synopsis

void *bfd zalloc2 (bfd *abfd, bfd size type nmemb, bfd size type size);

Description

Allocate a block of *nmemb* elements of *size* bytes each of zeroed memory attached to abfd and return a pointer to it.

2.14.1.16 bfd_calc_gnu_debuglink_crc32

Synopsis

```
unsigned long bfd_calc_gnu_debuglink_crc32
  (unsigned long crc, const unsigned char *buf, bfd_size_type len);
```

Description

Computes a CRC value as used in the .gnu_debuglink section. Advances the previously computed crc value by computing and adding in the crc32 for len bytes of buf.

Returns

Return the updated CRC32 value.

2.14.1.17 bfd_get_debug_link_info_1

Synopsis

```
char *bfd get debug link info 1 (bfd *abfd, void *crc32 out);
```

Description

Extracts the lename and CRC32 value for any separate debug information le associated with abfd.

The $crc32_out$ parameter is an untyped pointer because this routine is used as a get_func_type function, but it is expected to be an unsigned long pointer.

Returns

The lename of the associated debug information le, or NULL if there is no such le. If the lename was found then the contents of $crc32_out$ are updated to hold the corresponding CRC32 value for the le.

The returned lename is allocated with malloc; freeing it is the responsibility of the caller.

2.14.1.18 bfd_get_debug_link_info

Synopsis

```
char *bfd_get_debug_link_info (bfd *abfd, unsigned long *crc32_out);
```

Description

Extracts the lename and CRC32 value for any separate debug information le associated with abfd.

Returns

The lename of the associated debug information le, or NULL if there is no such le. If the lename was found then the contents of $crc32_out$ are updated to hold the corresponding CRC32 value for the le.

The returned lename is allocated with malloc; freeing it is the responsibility of the caller.

2.14.1.19 bfd_get_alt_debug_link_info

Synopsis

```
char *bfd_get_alt_debug_link_info (bfd * abfd,
    bfd_size_type *buildid_len,
    bfd_byte **buildid_out);
```

Description

Fetch the lename and BuildID value for any alternate debuginfo associated with abfd. Return NULL if no such info found, otherwise return lename and update $buildid_len$ and $buildid_out$. The returned lename and build_id are allocated with mall oc; freeing them is the responsibility of the caller.

2.14.1.20 separate_debug_file_exists

Synopsis

```
bfd_boolean separate_debug_file_exists
  (char *name, void *crc32_p);
```

Description

Checks to see if name is a le and if its contents match crc32, which is a pointer to an unsigned I ong containing a CRC32.

The $crc32_p$ parameter is an untyped pointer because this routine is used as a check_func_type function.

2.14.1.21 separate_alt_debug_file_exists

Synopsis

```
bfd_boolean separate_alt_debug_file_exists
    (char *name, void *unused);
```

Description

Checks to see if name is a le.

2.14.1.22 find_separate_debug_file

Synopsis

```
char *find_separate_debug_file
  (bfd *abfd, const char *dir, bfd_boolean include_dirs,
    get_func_type get, check_func_type check, void *data);
```

Description

Searches for a debug information le corresponding to *abfd*.

The name of the separate debug info le is returned by the get function. This function scans various xed locations in the lesystem, including the le tree rooted at dir. If the $include_dirs$ parameter is true then the directory components of abfd's lename will be included in the searched locations.

data is passed unmodi ed to the get and check functions. It is generally used to implement build-id-like matching in the callback functions.

Returns

Returns the lename of the rst le to be found which receives a TRUE result from the *check* function. Returns NULL if no valid le could be found.

2.14.1.23 bfd_follow_gnu_debuglink

Synopsis

```
char *bfd_follow_gnu_debuglink (bfd *abfd, const char *dir);
```

Description

Takes a BFD and searches it for a <code>.gnu_debuglink</code> section. If this section is found, it examines the section for the name and checksum of a '.debug' le containing auxiliary debugging information. It then searches the <code>lesystem</code> for this <code>.debug</code> le in some standard locations, including the directory tree rooted at dir, and if found returns the full <code>lename</code>.

If dir is NULL, the search will take place starting at the current directory.

Returns

NULL on any errors or failure to locate the .debug le, otherwise a pointer to a heap-allocated string containing the lename. The caller is responsible for freeing this string.

2.14.1.24 bfd_follow_gnu_debugaltlink

Synopsis

```
char *bfd follow gnu_debugaltlink (bfd *abfd, const char *dir);
```

Description

Takes a BFD and searches it for a .gnu_debugaltlink section. If this section is found, it examines the section for the name of a le containing auxiliary debugging information. It then searches the lesystem for this le in a set of standard locations, including the directory tree rooted at dir, and if found returns the full lename.

If dir is NULL, the search will take place starting at the current directory.

Returns

NULL on any errors or failure to locate the debug le, otherwise a pointer to a heap-allocated string containing the lename. The caller is responsible for freeing this string.

2.14.1.25 bfd_create_gnu_debuglink_section

Synopsis

```
struct bfd_section *bfd_create_gnu_debuglink_section
  (bfd *abfd, const char *filename);
```

Description

Takes a BFD and adds a .gnu_debuglink section to it. The section is sized to be big enough to contain a link to the speci_ed filename.

Paturns

A pointer to the new section is returned if all is ok. Otherwise NULL is returned and bfd_error is set.

2.14.1.26 bfd_fill_in_gnu_debuglink_section

Synopsis

```
bfd_boolean bfd_fill_in_gnu_debuglink_section
  (bfd *abfd, struct bfd_section *sect, const char *filename);
```

Description

Takes a BFD and containing a .gnu_debuglink section SECT and $\$ Ils in the contents of the section to contain a link to the speci ed $\$ ilename. The $\$ lename should be relative to the current directory.

Returns

TRUE is returned if all is ok. Otherwise FALSE is returned and bfd_error is set.

2.14.1.27 get_build_id

Synopsis

```
struct bfd_build_id * get_build_id (bfd *abfd);
```

Description

Finds the build-id associated with abfd. If the build-id is extracted from the note section

then a build-id structure is built for it, using memory allocated to abfd, and this is then attached to the abfd.

Returns

Returns a pointer to the build-id structure if a build-id could be found. If no build-id is found NULL is returned and error code is set.

2.14.1.28 get_build_id_name

Synopsis

```
char * get_build_id_name (bfd *abfd, void *build_id_out_p)
```

Description

Searches abfd for a build-id, and then constructs a pathname from it. The path is computed as .build-id/NN/NN+NN.debug where NNNN+NN is the build-id value as a hexadecimal string.

Returns

Returns the constructed lename or NULL upon error. It is the caller's responsibility to free the memory used to hold the lename. If a lename is returned then the $build_id_out_p$ parameter (which points to a struct bfd_build_id pointer) is set to a pointer to the build_id structure.

2.14.1.29 check_build_id_file

Synopsis

bfd_boolean check_build_id_file (char *name, void *buildid_p);

Description

Checks to see if *name* is a readable—le and if its build-id matches *buildid*.

Returns

Returns TRUE if the le exists, is readable, and contains a build-id which matches the build-id pointed at by $build_id_p$ (which is really a struct bfd_build_id **).

2.14.1.30 bfd_follow_build_id_debuglink

Synopsis

```
char *bfd_follow_build_id_debuglink (bfd *abfd, const char *dir);
```

Description

Takes abfd and searches it for a .note.gnu.build-id section. If this section is found, it extracts the value of the NT_GNU_BUILD_ID note, which should be a hexadecimal value NNNN+NN (for 32+ hex digits). It then searches the lesystem for a le named .build-id/NN/NN+NN.debug in a set of standard locations, including the directory tree rooted at dir. The lename of the rst matching le to be found is returned. A matching le should contain a .note.gnu.build-id section with the same NNNN+NN note as abfd, although this check is currently not implemented.

If dir is NULL, the search will take place starting at the current directory.

Returns

NULL on any errors or failure to locate the debug le, otherwise a pointer to a heap-allocated string containing the lename. The caller is responsible for freeing this string.

2.15 Implementation details

2.15.1 Internal functions

Description

These routines are used within BFD. They are not intended for export, but are documented here for completeness.

2.15.1.1 bfd_write_bigendian_4byte_int

Synopsis

```
bfd_boolean bfd_write_bigendian_4byte_int (bfd *, unsigned int);
```

Description

Write a 4 byte integer i to the output BFD abfd, in big endian order regardless of what else is going on. This is useful in archives.

2.15.1.2 bfd_put_size

2.15.1.3 bfd_get_size

Description

These macros as used for reading and writing raw data in sections; each access (except for bytes) is vectored through the target format of the BFD and mangled accordingly. The mangling performs any necessary endian translations and removes alignment restrictions. Note that types accepted and returned by these macros are identical so they can be swapped around in macros | for example, `libaout.h' de nes GET_WORD to either bfd_get_32 or bfd_get_64.

In the put routines, *val* must be a bfd_vma. If we are on a system without prototypes, the caller is responsible for making sure that is true, with a cast if necessary. We don't cast them in the macro de nitions because that would prevent I int or gcc -Wal I from detecting sins such as passing a pointer. To detect calling these with less than a bfd_vma, use gcc -Wconversi on on a host with 64 bit bfd_vma's.

```
/* Byte swapping macros for user section data. */
#define bfd_put_8(abfd, val, ptr) \
    ((void) (*((unsigned char *) (ptr)) = (val) & 0xff))
#define bfd_put_signed_8 \
    bfd_put_8
#define bfd_get_8(abfd, ptr) \
    (*(const unsigned char *) (ptr) & 0xff)
#define bfd_get_signed_8(abfd, ptr) \
    (((*(const unsigned char *) (ptr) & 0xff) ^ 0x80) - 0x80)
#define bfd_put_16(abfd, val, ptr) \
    BFD_SEND (abfd, bfd_putx16, ((val), (ptr)))
#define bfd_put_signed_16 \
    bfd_put_16
```

```
#define bfd_get_16(abfd, ptr) \
 BFD_SEND (abfd, bfd_getx16, (ptr))
#define bfd_get_signed_16(abfd, ptr) \
 BFD_SEND (abfd, bfd_getx_signed_16, (ptr))
#define bfd_put_32(abfd, val, ptr) \
 BFD_SEND (abfd, bfd_putx32, ((val), (ptr)))
#define bfd_put_signed_32 \
 bfd_put_32
#define bfd_get_32(abfd, ptr) \
 BFD_SEND (abfd, bfd_getx32, (ptr))
#define bfd_get_signed_32(abfd, ptr) \
 BFD_SEND (abfd, bfd_getx_signed_32, (ptr))
#define bfd_put_64(abfd, val, ptr) \
 BFD_SEND (abfd, bfd_putx64, ((val), (ptr)))
#define bfd_put_signed_64 \
 bfd_put_64
#define bfd_get_64(abfd, ptr) \
 BFD_SEND (abfd, bfd_getx64, (ptr))
#define bfd_get_signed_64(abfd, ptr) \
 BFD SEND (abfd, bfd getx signed 64, (ptr))
#define bfd_get(bits, abfd, ptr)
  ((bits) == 8? (bfd_vma) bfd_get_8 (abfd, ptr)
  : (bits) == 16 ? bfd_get_16 (abfd, ptr)
  : (bits) == 32 ? bfd_get_32 (abfd, ptr)
  : (bits) == 64 ? bfd_get_64 (abfd, ptr)
  : (abort (), (bfd_vma) - 1))
#define bfd_put(bits, abfd, val, ptr)
  ((bits) == 8 ? bfd_put_8 (abfd, val, ptr)
  : (bits) == 16 ? bfd_put_16 (abfd, val, ptr)
  : (bits) == 32 ? bfd_put_32 (abfd, val, ptr)
  : (bits) == 64 ? bfd_put_64 (abfd, val, ptr)
  : (abort (), (void) 0))
```

2.15.1.4 bfd_h_put_size

Description

These macros have the same function as their bfd_get_x brethren, except that they are used for removing information for the header records of object les. Believe it or not, some object les keep their header records in big endian order and their data in little endian order.

```
#define bfd_h_put_8(abfd, val, ptr) \
 bfd_put_8 (abfd, val, ptr)
#define bfd_h_put_signed_8(abfd, val, ptr) \
 bfd_put_8 (abfd, val, ptr)
#define bfd_h_get_8(abfd, ptr) \
 bfd get 8 (abfd, ptr)
#define bfd_h_get_signed_8(abfd, ptr) \
 bfd_get_signed_8 (abfd, ptr)
#define bfd_h_put_16(abfd, val, ptr) \
 BFD_SEND (abfd, bfd_h_putx16, (val, ptr))
#define bfd_h_put_signed_16 \
 bfd_h_put_16
#define bfd_h_get_16(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx16, (ptr))
#define bfd_h_get_signed_16(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx_signed_16, (ptr))
#define bfd_h_put_32(abfd, val, ptr) \
 BFD_SEND (abfd, bfd_h_putx32, (val, ptr))
#define bfd h put signed 32 \
 bfd_h_put_32
#define bfd_h_get_32(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx32, (ptr))
#define bfd_h_get_signed_32(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx_signed_32, (ptr))
#define bfd_h_put_64(abfd, val, ptr) \
 BFD_SEND (abfd, bfd_h_putx64, (val, ptr))
#define bfd h put signed 64 \
 bfd_h_put_64
#define bfd h get 64(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx64, (ptr))
#define bfd h get signed 64(abfd, ptr) \
 BFD_SEND (abfd, bfd_h_getx_signed_64, (ptr))
/* Aliases for the above, which should eventually go away.
#define H PUT 64 bfd h put 64
#define H PUT 32 bfd h put 32
#define H_PUT_16 bfd_h_put_16
#define H PUT 8
                  bfd h put 8
#define H PUT S64 bfd h put signed 64
#define H PUT S32 bfd h put signed 32
#define H PUT S16 bfd h put signed 16
#define H_PUT_S8 bfd_h_put_signed_8
```

```
#define H_GET_64 bfd_h_get_64
#define H_GET_32 bfd_h_get_32
#define H_GET_16 bfd_h_get_16
#define H_GET_8 bfd_h_get_8
#define H_GET_S64 bfd_h_get_signed_64
#define H_GET_S32 bfd_h_get_signed_32
#define H_GET_S16 bfd_h_get_signed_16
#define H_GET_S8 bfd_h_get_signed_8
```

2.15.1.5 bfd_log2

Synopsis

unsigned int bfd_log2 (bfd_vma x);

Description

Return the log base 2 of the value supplied, rounded up. E.g., an x of 1025 returns 11. A x of 0 returns 0.

2.16 File caching

The le caching mechanism is embedded within BFD and allows the application to open as many BFDs as it wants without regard to the underlying operating system's le descriptor limit (often as low as 20 open les). The module in cache. c maintains a least recently used list of bfd_cache_max_open les, and exports the name bfd_cache_l ookup, which runs around and makes sure that the required BFD is open. If not, then it chooses a le to close, closes it and opens the one wanted, returning its le handle.

2.16.1 Caching functions

2.16.1.1 bfd_cache_init

Synopsis

bfd_boolean bfd_cache_init (bfd *abfd);

Description

Add a newly opened BFD to the cache.

2.16.1.2 bfd_cache_close

Synopsis

bfd boolean bfd cache close (bfd *abfd);

Description

Remove the BFD *abfd* from the cache. If the attached le is open, then close it too.

Returns

FALSE is returned if closing the le fails, TRUE is returned if all is well.

2.16.1.3 bfd_cache_close_all

Synopsis

bfd_boolean bfd_cache_close_all (void);

Description

Remove all BFDs from the cache. If the attached le is open, then close it too.

Returns

FALSE is returned if closing one of the le fails, TRUE is returned if all is well.

2.16.1.4 bfd_open_file

Synopsis

FILE* bfd_open_file (bfd *abfd);

Description

2.17 Linker Functions

The linker uses three special entry points in the BFD target vector. It is not necessary to write special routines for these entry points when creating a new BFD back end, since generic versions are provided. However, writing them can speed up linking and make it use signi cantly less runtime memory.

The rst routine creates a hash table used by the other routines. The second routine adds the symbols from an object le to the hash table. The third routine takes all the object les and links them together to create the output le. These routines are designed so that the linker proper does not need to know anything about the symbols in the object les that it is linking. The linker merely arranges the sections as directed by the linker script and lets BFD handle the details of symbols and relocs.

The second routine and third routines are passed a pointer to a struct bfd_link_info structure (de ned in bfdlink.h) which holds information relevant to the link, including the linker hash table (which was created by the rst routine) and a set of callback functions to the linker proper.

The generic linker routines are in Linker. c, and use the header—le genlink. h. As of this writing, the only back ends which have implemented versions of these routines are a.out (in aoutx.h) and ECOFF (in ecoff.c). The a.out routines are used as examples throughout this section.

2.17.1 Creating a linker hash table

The linker routines must create a hash table, which must be derived from struct bfd_link_hash_table described in bfdlink.c. See Section 2.18 [Hash Tables], page 187, for information on how to create a derived hash table. This entry point is called using the target vector of the linker output le.

The _bfd_link_hash_table_create entry point must allocate and initialize an instance of the desired hash table. If the back end does not require any additional information to be stored with the entries in the hash table, the entry point may simply create a struct bfd_link_hash_table. Most likely, however, some additional information will be needed.

For example, with each entry in the hash table the a.out linker keeps the index the symbol has in the nal output le (this index number is used so that when doing a relocatable link the symbol index used in the output le can be quickly lled in when copying over a reloc). The a.out linker code de nes the required structures and functions for a hash table derived from struct bfd_link_hash_table. The a.out linker hash table is created by the function NAME(aout, link_hash_table_create); it simply allocates space for the hash table, initializes it, and returns a pointer to it.

When writing the linker routines for a new back end, you will generally not know exactly which elds will be required until you have nished. You should simply create a new hash table which de nes no additional elds, and then simply add elds as they become necessary.

2.17.2 Adding symbols to the hash table

The linker proper will call the _bfd_l i nk_add_symbol s entry point for each object le or archive which is to be linked (typically these are the les named on the command line, but some may also come from the linker script). The entry point is responsible for examining the le. For an object le, BFD must add any relevant symbol information to the hash table. For an archive, BFD must determine which elements of the archive should be used and adding them to the link.

The a.out version of this entry point is NAME (aout, I i nk_add_symbols).

2.17.2.1 Differing file formats

Normally all the les involved in a link will be of the same format, but it is also possible to link together di erent format object les, and the back end must support that. The _bfd_link_add_symbols entry point is called via the target vector of the le to be added. This has an important consequence: the function may not assume that the hash table is the type created by the corresponding _bfd_link_hash_table_create vector. All the _ bfd_link_add_symbols function can assume about the hash table is that it is derived from struct bfd_link_hash_table.

Sometimes the _bfd_link_add_symbols function must store some information in the hash table entry to be used by the _bfd_final_link function. In such a case the output bfd xvec must be checked to make sure that the hash table was created by an object le of the same format.

The _bfd_fi nal _l i nk routine must be prepared to handle a hash entry without any extra information added by the _bfd_l i nk_add_symbol s function. A hash entry without extra information will also occur when the linker script directs the linker to create a symbol. Note that, regardless of how a hash table entry is added, all the _elds will be initialized to some sort of null value by the hash table entry initialization function.

See ecoff_link_add_externals for an example of how to check the output bfd before saving information (in this case, the ECOFF external symbol debugging information) in a hash table entry.

2.17.2.2 Adding symbols from an object file

When the _bfd_link_add_symbols routine is passed an object le, it must add all externally visible symbols in that object le to the hash table. The actual work of adding the symbol to the hash table is normally handled by the function _bfd_generic_link_add_one_symbol. The _bfd_link_add_symbols routine is responsible for reading all the

symbols from the object—le and passing the correct information to _bfd_generic_link_ add_one_symbol.

The _bfd_link_add_symbols routine should not use bfd_canonicalize_symtab to read the symbols. The point of providing this routine is to avoid the overhead of converting the symbols into generic asymbol structures.

_bfd_generic_link_add_one_symbol handles the details of combining common symbols, warning about multiple de nitions, and so forth. It takes arguments which describe the symbol to add, notably symbol ags, a section, and an o set. The symbol ags include such things as BSF_WEAK or BSF_INDIRECT. The section is a section in the object le, or something like bfd_und_section_ptr for an unde ned symbol or bfd_com_section_ptr for a common symbol.

If the _bfd_fi nal_link routine is also going to need to read the symbol information, the _bfd_link_add_symbols routine should save it somewhere attached to the object le BFD. However, the information should only be saved if the keep_memory eld of the info argument is TRUE, so that the -no-keep-memory linker switch is elective.

The a.out function which adds symbols from an object le is aout_link_add_object_ symbols, and most of the interesting work is in aout_link_add_symbols. The latter saves pointers to the hash tables entries created by _bfd_generic_link_add_one_symbol indexed by symbol number, so that the _bfd_final_link routine does not have to call the hash table lookup routine to locate the entry.

2.17.2.3 Adding symbols from an archive

When the _bfd_link_add_symbols routine is passed an archive, it must look through the symbols de ned by the archive and decide which elements of the archive should be included in the link. For each such element it must call the add_archive_element linker callback, and it must add the symbols from the object le to the linker hash table. (The callback may in fact indicate that a replacement BFD should be used, in which case the symbols from that BFD should be added to the linker hash table instead.)

In most cases the work of looking through the symbols in the archive should be done by the _bfd_generic_link_add_archive_symbols function. _bfd_generic_link_add_archive_symbols is passed a function to call to make the _nal decision about adding an archive element to the link and to do the actual work of adding the symbols to the linker hash table. If the element is to be included, the add_archive_element linker callback routine must be called with the element as an argument, and the element's symbols must be added to the linker hash table just as though the element had itself been passed to the _bfd_link_add_symbols function.

When the a.out _bfd_link_add_symbols function receives an archive, it calls _bfd_generic_link_add_archive_symbols passing aout_link_check_archive_element as the function argument. aout_link_check_archive_element calls aout_link_check_ar_symbols. If the latter decides to add the element (an element is only added if it provides a real, non-common, de nition for a previously unde ned or common symbol) it calls the add_archive_element callback and then aout_link_check_archive_element calls aout_link_add_symbols to actually add the symbols to the linker hash table possibly those of a substitute BFD, if the add_archive_element callback avails itself of that option.

The ECOFF back end is unusual in that it does not normally call _bfd_generic_link_ add_archive_symbols, because ECOFF archives already contain a hash table of symbols. The ECOFF back end searches the archive itself to avoid the overhead of creating a new hash table.

2.17.3 Performing the final link

When all the input les have been processed, the linker calls the _bfd_fi nal_link entry point of the output BFD. This routine is responsible for producing the _nal output le, which has several aspects. It must relocate the contents of the input sections and copy the data into the output sections. It must build an output symbol table including any local symbols from the input les and the global symbols from the hash table. When producing relocatable output, it must modify the input relocs and write them into the output le. There may also be object format dependent work to be done.

The linker will also call the write_object_contents entry point when the BFD is closed. The two entry points must work together in order to produce the correct output le.

The details of how this works are inevitably dependent upon the speciec object. It format. The alout bfd final link routine is NAME (aout, final link).

2.17.3.1 Information provided by the linker

Before the linker calls the _bfd_fi nal _l i nk entry point, it sets up some data structures for the function to use.

The input_bfds eld of the bfd_link_info structure will point to a list of all the input les included in the link. These les are linked through the link. next eld of the bfd structure.

Each section in the output le will have a list of link_order structures attached to the map_head. link_order eld (the link_order structure is de ned in bfdlink.h). These structures describe how to create the contents of the output section in terms of the contents of various input sections, Il constants, and, eventually, other types of information. They also describe relocs that must be created by the BFD backend, but do not correspond to any input le; this is used to support -Ur, which builds constructors while generating a relocatable object le.

2.17.3.2 Relocating the section contents

The _bfd_fi nal_link function should look through the link_order structures attached to each section of the output le. Each link_order structure should either be handled specially, or it should be passed to the function _bfd_defaul t_link_order which will do the right thing (bfd defaul t link order is de ned in linker.c).

For e ciency, a link_order of type bfd_indirect_link_order whose associated section belongs to a BFD of the same format as the output BFD must be handled specially. This type of link_order describes part of an output section in terms of a section belonging to one of the input les. The _bfd_final_link function should read the contents of the section and any associated relocs, apply the relocs to the section contents, and write out the modi ed section contents. If performing a relocatable link, the relocs themselves must also be modi ed and written out.

The functions _bfd_rel ocate_contents and _bfd_fi nal_link_rel ocate provide some general support for performing the actual relocations, notably over ow checking. Their arguments include information about the symbol the relocation is against and a rel oc_howto_type argument which describes the relocation to perform. These functions are de ned in rel oc. c.

The a.out function which handles reading, relocating, and writing section contents is aout_link_input_section. The actual relocation is done in aout_link_input_section_std and aout_link_input_section_ext.

2.17.3.3 Writing the symbol table

The _bfd_fi nal_l i nk function must gather all the symbols in the input les and write them out. It must also write out all the symbols in the global hash table. This must be controlled by the strip and discard elds of the bfd_l i nk_i nfo structure.

The local symbols of the input les will not have been entered into the linker hash table. The _bfd_fi nal_link routine must consider each input le and include the symbols in the output le. It may be convenient to do this when looking through the link_order structures, or it may be done by stepping through the input_bfds list.

The _bfd_fi nal_l i nk routine must also traverse the global hash table to gather all the externally visible symbols. It is possible that most of the externally visible symbols may be written out when considering the symbols of each input le, but it is still necessary to traverse the hash table since the linker script may have de ned some symbols that are not in any of the input les.

The strip eld of the bfd_link_info structure controls which symbols are written out. The possible values are listed in bfdlink. h. If the value is strip_some, then the keep_hash eld of the bfd_link_info structure is a hash table of symbols to keep; each symbol should be looked up in this hash table, and only symbols which are present should be included in the output le.

If the strip eld of the bfd_link_info structure permits local symbols to be written out, the discard eld is used to further controls which local symbols are included in the output le. If the value is discard_l, then all local symbols which begin with a certain pre x are discarded; this is controlled by the bfd_is_local_label_name entry point.

The a.out backend handles symbols by calling aout_link_write_symbols on each input BFD and then traversing the global hash table with the function aout_link_write_other_symbol. It builds a string table while writing out the symbols, which is written to the output le at the end of NAME (aout, final_link).

2.17.3.4 bfd_link_split_section

Synopsis

```
bfd_boolean bfd_link_split_section (bfd *abfd, asection *sec);
```

Description

Return nonzero if sec should be split during a reloceatable or nal link.

```
#define bfd_link_split_section(abfd, sec) \
    BFD_SEND (abfd, _bfd_link_split_section, (abfd, sec))
```

2.17.3.5 bfd_section_already_linked

Synopsis

Description

Check if data has been already linked during a reloceatable or $\$ nal link. Return TRUE if it has.

```
#define bfd_section_already_linked(abfd, sec, info) \
BFD_SEND (abfd, _section_already_linked, (abfd, sec, info))
```

2.17.3.6 bfd_generic_define_common_symbol

Synopsis

```
bfd_boolean bfd_generic_define_common_symbol
  (bfd *output_bfd, struct bfd_link_info *info,
    struct bfd_link_hash_entry *h);
```

Description

Convert common symbol h into a de ned symbol. Return TRUE on success and FALSE on failure.

```
#define bfd_define_common_symbol(output_bfd, info, h) \
BFD_SEND (output_bfd, _bfd_define_common_symbol, (output_bfd, info, h))
```

2.17.3.7 bfd_generic_define_start_stop

Synopsis

```
struct bfd_link_hash_entry *bfd_generic_define_start_stop
  (struct bfd_link_info *info,
    const char *symbol, asection *sec);
```

Description

De ne a __start, __stop, .startof. or .sizeof. symbol. Return the symbol or NULL if no such unde ned symbol exists.

```
#define bfd_define_start_stop(output_bfd, info, symbol, sec) \
BFD_SEND (output_bfd, _bfd_define_start_stop, (info, symbol, sec))
```

2.17.3.8 bfd_find_version_for_sym

Synopsis

```
struct bfd_elf_version_tree * bfd_find_version_for_sym
  (struct bfd_elf_version_tree *verdefs,
    const char *sym_name, bfd_boolean *hide);
```

Description

Search an elf version script tree for symbol versioning info and export / don't-export status

for a given symbol. Return non-NULL on success and NULL on failure; also sets the output 'hi de' boolean parameter.

2.17.3.9 bfd_hide_sym_by_version

Synopsis

```
bfd_boolean bfd_hide_sym_by_version
  (struct bfd_elf_version_tree *verdefs, const char *sym_name);
```

Description

Search an elf version script tree for symbol versioning info for a given symbol. Return TRUE if the symbol is hidden.

2.17.3.10 bfd_link_check_relocs

Synopsis

```
bfd_boolean bfd_link_check_relocs
  (bfd *abfd, struct bfd_link_info *info);
```

Description

Checks the relocs in ABFD for validity. Does not execute the relocs. Return TRUE if everything is OK, FALSE otherwise. This is the external entry point to this code.

2.17.3.11 _bfd_generic_link_check_relocs

Synopsis

```
bfd_boolean _bfd_generic_link_check_relocs
  (bfd *abfd, struct bfd_link info *info);
```

Description

Stub function for targets that do not implement reloc checking. Return TRUE. This is an internal function. It should not be called from outside the BFD library.

2.17.3.12 bfd_merge_private_bfd_data

Synopsis

```
bfd_boolean bfd_merge_private_bfd_data
   (bfd *ibfd, struct bfd_link_info *info);
```

Description

Merge private BFD information from the BFD ibfd to the the output le BFD when linking. Return TRUE on success, FALSE on error. Possible error returns are:

ullet bfd_error_no_memory - Not enough memory exists to create private data for obfd.

2.17.3.13 _bfd_generic_verify_endian_match

Synopsis

```
bfd_boolean _bfd_generic_verify_endian_match
    (bfd *ibfd, struct bfd_link_info *info);
```

Description

Can be used from / for bfd_merge_private_bfd_data to check that endianness matches between input and output le. Returns TRUE for a match, otherwise returns FALSE and emits an error.

2.18 Hash Tables

BFD provides a simple set of hash table functions. Routines are provided to initialize a hash table, to free a hash table, to look up a string in a hash table and optionally create an entry for it, and to traverse a hash table. There is currently no routine to delete an string from a hash table.

The basic hash table does not permit any data to be stored with a string. However, a hash table is designed to present a base class from which other types of hash tables may be derived. These derived types may store additional information with the string. Hash tables were implemented in this way, rather than simply providing a data pointer in a hash table entry, because they were designed for use by the linker back ends. The linker may create thousands of hash table entries, and the overhead of allocating private data and storing and following pointers becomes noticeable.

The basic hash table code is in hash, c.

2.18.1 Creating and freeing a hash table

To create a hash table, create an instance of a struct bfd_hash_table (de ned in bfd.h) and call bfd_hash_table_i ni t (if you know approximately how many entries you will need, the function bfd_hash_table_i ni t_n, which takes a *size* argument, may be used). bfd_hash_table_i ni t returns FALSE if some sort of error occurs.

The function bfd_hash_table_init take as an argument a function to use to create new entries. For a basic hash table, use the function bfd_hash_newfunc. See Section 2.18.4 [Deriving a New Hash Table Type], page 188, for why you would want to use a di erent value for this argument.

bfd_hash_table_i nit will create an objalloc which will be used to allocate new entries. You may allocate memory on this objalloc using bfd_hash_allocate.

Use bfd_hash_table_free to free up all the memory that has been allocated for a hash table. This will not free up the struct bfd_hash_table itself, which you must provide.

Use bfd_hash_set_defaul t_si ze to set the default size of hash table to use.

2.18.2 Looking up or entering a string

The function bfd_hash_I ookup is used both to look up a string in the hash table and to create a new entry.

If the *create* argument is FALSE, bfd_hash_I ookup will look up a string. If the string is found, it will returns a pointer to a struct bfd_hash_entry. If the string is not found in the table bfd_hash_I ookup will return NULL. You should not modify any of the elds in the returns struct bfd_hash_entry.

If the *create* argument is TRUE, the string will be entered into the hash table if it is not already there. Either way a pointer to a struct bfd_hash_entry will be returned, either to the existing structure or to a newly created one. In this case, a NULL return means that an error occurred.

If the *create* argument is TRUE, and a new entry is created, the *copy* argument is used to decide whether to copy the string onto the hash table objalloc or not. If *copy* is passed as FALSE, you must be careful not to deallocate or modify the string as long as the hash table exists.

2.18.3 Traversing a hash table

The function bfd_hash_traverse may be used to traverse a hash table, calling a function on each element. The traversal is done in a random order.

bfd_hash_traverse takes as arguments a function and a generic void * pointer. The function is called with a hash table entry (a struct bfd_hash_entry *) and the generic pointer passed to bfd_hash_traverse. The function must return a bool ean value, which indicates whether to continue traversing the hash table. If the function returns FALSE, bfd_hash_traverse will stop the traversal and return immediately.

2.18.4 Deriving a new hash table type

Many uses of hash tables want to store additional information which each entry in the hash table. Some also nd it convenient to store additional information with the hash table itself. This may be done using a derived hash table.

Since C is not an object oriented language, creating a derived hash table requires sticking together some boilerplate routines with a few di erences speci c to the type of hash table you want to create.

An example of a derived hash table is the linker hash table. The structures for this are de ned in bfdlink.h. The functions are in linker.c.

You may also derive a hash table from an already derived hash table. For example, the a.out linker backend code uses a hash table derived from the linker hash table.

2.18.4.1 Define the derived structures

You must de ne a structure for an entry in the hash table, and a structure for the hash table itself.

The rst eld in the structure for an entry in the hash table must be of the type used for an entry in the hash table you are deriving from. If you are deriving from a basic hash table this is struct bfd_hash_entry, which is de ned in bfd. h. The rst eld in the structure for the hash table itself must be of the type of the hash table you are deriving from itself. If you are deriving from a basic hash table, this is struct bfd_hash_table.

For example, the linker hash table de nes struct bfd_link_hash_entry (in bfdlink.h). The rst eld, root, is of type struct bfd_hash_entry. Similarly, the rst eld in struct bfd_link_hash_table, table, is of type struct bfd_hash_table.

2.18.4.2 Write the derived creation routine

You must write a routine which will create and initialize an entry in the hash table. This routine is passed as the function argument to bfd_hash_table_i nit.

In order to permit other hash tables to be derived from the hash table you are creating, this routine must be written in a standard way.

The rst argument to the creation routine is a pointer to a hash table entry. This may be NULL, in which case the routine should allocate the right amount of space. Otherwise the space has already been allocated by a hash table type derived from this one.

After allocating space, the creation routine must call the creation routine of the hash table type it is derived from, passing in a pointer to the space it just allocated. This will initialize any elds used by the base hash table.

Finally the creation routine must initialize any local elds for the new hash table type.

Here is a boilerplate example of a creation routine. *function_name* is the name of the routine. *entry_type* is the type of an entry in the hash table you are creating. *base_newfunc* is the name of the creation routine of the hash table type your hash table is derived from.

```
struct bfd_hash_entry *
function_name (struct bfd_hash_entry *entry,
                     struct bfd_hash_table *table,
                     const char *string)
 struct entry_type *ret = (entry_type *) entry;
 /* Allocate the structure if it has not already been allocated by a
   derived class. */
 if (ret == NULL)
   {
     ret = bfd_hash_allocate (table, sizeof (* ret));
     if (ret == NULL)
       return NULL;
   }
/* Call the allocation method of the base class. */
 ret = ((entry_type *)
         base_newfunc ((struct bfd_hash_entry *) ret, table, string));
/* Initialize the local fields here. */
 return (struct bfd_hash_entry *) ret;
}
```

Description

The creation routine for the linker hash table, which is in linker.c, looks just like this example. <code>function_name</code> is <code>_bfd_link_hash_newfunc</code>. <code>entry_type</code> is struct <code>bfd_link_hash_newfunc</code>, the creation routine for a basic hash table.

_bfd_link_hash_newfunc also initializes the local elds in a linker hash table entry: type, written and next.

2.18.4.3 Write other derived routines

You will want to write other routines for your new hash table, as well.

You will want an initialization routine which calls the initialization routine of the hash table you are deriving from and initializes any other local elds. For the linker hash table, this is _bfd_l i nk_hash_table_i ni t in l i nker. c.

You will want a lookup routine which calls the lookup routine of the hash table you are deriving from and casts the result. The linker hash table uses bfd_l i nk_hash_l ookup in l i nker. c (this actually takes an additional argument which it uses to decide how to return the looked up value).

You may want a traversal routine. This should just call the traversal routine of the hash table you are deriving from with appropriate casts. The linker hash table uses bfd_link_hash_traverse in linker.c.

These routines may simply be de ned as macros. For example, the a.out backend linker hash table, which is derived from the linker hash table, uses macros for the lookup and traversal routines. These are aout_link_hash_lookup and aout_link_hash_traverse in aoutx.h.

3 BFD back ends

3.1 What to Put Where

All of BFD lives in one directory.

3.2 a.out backends

Description

BFD supports a number of di erent avours of a.out format, though the major di erences are only the sizes of the structures on disk, and the shape of the relocation information.

The support is split into a basic support le `aoutx. h' and other les which derive functions from the base. One derivation le is `aoutf1. h' (for a.out avour 1), and adds to the basic a.out functions support for sun3, sun4, 386 and 29k a.out les, to create a target jump vector for a speci c target.

This information is further split out into more speci c les for each machine, including `sunos. c' for sun3 and sun4, `newsos3. c' for the Sony NEWS, and `demo64. c' for a demonstration of a 64 bit a.out format.

The base le `aoutx.h' de nes general mechanisms for reading and writing records to and from disk and various other methods which BFD requires. It is included by `aout32.c' and `aout64.c' to form the names aout_32_swap_exec_header_i n, aout_64_swap_exec_header_i n, etc.

As an example, this is what goes on to make the back end for a sun4, from `aout32. c':

```
#define ARCH_SIZE 32
#include "aoutx.h"
```

Which exports names:

```
aout_32_canoni calize_reloc
aout_32_fi nd_nearest_line
aout_32_get_li neno
aout_32_get_reloc_upper_bound
```

from `sunos. c':

requires all the names from `aout32. c', and produces the jump vector

```
sparc_aout_sunos_be_vec
```

The le`host-aout.c' is a special case. It is for a large set of hosts that use \more or less standard" a.out les, and for which cross-debugging is not interesting. It uses the standard 32-bit a.out support routines, but determines the le o sets and addresses of the text, data, and BSS sections, the machine architecture and machine type, and the entry point address, in a host-dependent manner. Once these values have been determined, generic code is used to handle the object le.

When porting it to run on a new system, you must supply:

```
HOST_PAGE_SIZE
HOST_SEGMENT_SIZE
HOST_MACHINE_ARCH (optional)
HOST_MACHINE_MACHINE (optional)
HOST_TEXT_START_ADDR
HOST_STACK_END_ADDR
```

in the le`../include/sys/h-xxx.h' (for your host). These values, plus the structures and macros de ned in `a. out.h' on your host system, will produce a BFD target that will access ordinary a.out les on your host. To con gure a new machine to use `host-aout.c', specify:

```
TDEFAULTS = -DDEFAULT_VECTOR=host_aout_big_vec
TDEPFILES= host-aout.o trad-core.o
```

in the `confi g/xxx.mt' le, and modify `confi gure. ac' to use the `xxx.mt' le (by setting "bfd_target=XXX") when your con guration is selected.

3.2.1 Relocations

Description

The le `aoutx. h' provides for both the *standard* and *extended* forms of a.out relocation records.

The standard records contain only an address, a symbol index, and a type eld. The extended records (used on 29ks and sparcs) also have a full integer for an addend.

3.2.2 Internal entry points

Description

`aoutx. h' exports several routines for accessing the contents of an a.out le, which are gathered and exported in turn by various format speci c les (eg sunos.c).

3.2.2.1 aout_size_swap_exec_header_in

Synopsis

```
void aout_size_swap_exec_header_in,
  (bfd *abfd,
    struct external_exec *bytes,
    struct internal_exec *execp);
```

Description

Swap the information in an executable header raw_bytes taken from a raw byte stream memory image into the internal exec header structure execp.

3.2.2.2 aout_size_swap_exec_header_out

Synopsis

```
void aout_size_swap_exec_header_out
  (bfd *abfd,
    struct internal_exec *execp,
    struct external_exec *raw_bytes);
```

Description

Swap the information in an internal exec header structure execp into the bu er raw_bytes ready for writing to disk.

3.2.2.3 aout_size_some_aout_object_p

Synopsis

```
const bfd_target *aout_size_some_aout_object_p
  (bfd *abfd,
    struct internal_exec *execp,
    const bfd_target *(*callback_to_real_object_p) (bfd *));
```

Description

Some a.out variant thinks that the le open in *abfd* checking is an a.out le. Do some more checking, and set up for access if it really is. Call back to the calling environment's "nish up" function just before returning, to handle any last-minute setup.

3.2.2.4 aout_size_mkobject

Synopsis

```
bfd_boolean aout_size_mkobject, (bfd *abfd);
```

Description

Initialize BFD abfd for use with a.out les.

3.2.2.5 aout_size_machine_type

Synopsis

```
enum machi ne_type aout_size_machi ne_type
  (enum bfd_archi tecture arch,
   unsi gned long machi ne,
   bfd_bool ean *unknown);
```

Description

Keep track of machine architecture and machine type for a.out's. Return the machine_type for a particular architecture and machine, or M_UNKNOWN if that exact architecture and machine can't be represented in a.out format.

If the architecture is understood, machine type 0 (default) is always understood.

3.2.2.6 aout_size_set_arch_mach

Synopsis

```
bfd_boolean aout_size_set_arch_mach,
   (bfd *,
      enum bfd_architecture arch,
      unsigned long machine);
```

Description

Set the architecture and the machine of the BFD *abfd* to the values *arch* and *machine*. Verify that *abfd*'s format can support the architecture required.

3.2.2.7 aout_size_new_section_hook

Synopsis

```
bfd_boolean aout_size_new_section_hook,
    (bfd *abfd,
        asection *newsect);
```

Description

Called by the BFD in response to a bfd_make_section request.

3.3 coff backends

BFD supports a number of di erent avours of co format. The major di erences between formats are the sizes and alignments of elds in structures on disk, and the occasional extra eld.

Co in all its varieties is implemented with a few common les and a number of implementation speci c les. For example, The 88k bcs co format is implemented in the le `coff-m88k.c'. This le #includes `coff/m88k.h' which de nes the external structure of the co format for the 88k, and `coff/internal.h' which de nes the internal structure. `coff-m88k.c' also de nes the relocations used by the 88k format See Section 2.10 [Relocations], page 55.

The Intel i960 processor version of co is implemented in `coff-i 960.c'. This le has the same structure as `coff-m88k.c', except that it includes `coff/i 960.h' rather than `coff-m88k.h'.

3.3.1 Porting to a new version of coff

The recommended method is to select from the existing implementations the version of co which is most like the one you want to use. For example, we'll say that i386 co is the one you select, and that your co avour is called foo. Copy `i 386coff. c' to `foocoff. c', copy `../i ncl ude/coff/i 386. h' to `../i ncl ude/coff/foo. h', and add the lines to `targets. c' and `Makefile. i n' so that your new back end is used. Alter the shapes of the structures in `../i ncl ude/coff/foo. h' so that they match what you need. You will probably also have to add #i fdefs to the code in `coff/i nternal. h' and `coffcode. h' if your version of co is too wild.

You can verify that your new BFD backend works quite simply by building `obj dump' from the `bi nutils' directory, and making sure that its version of what's going on and your host system's idea (assuming it has the pretty standard co dump utility, usually called att-dump

The generic routines are in `coffgen. c'. These routines work for any Co target. They use some hooks into the target speci c code; the hooks are in a bfd_coff_backend_data structure, one of which exists for each target.

The essentially similar target-specied routines are in `coffcode. h'. This header le includes executable C code. The various Coetargets est include the appropriate Coetargets executable conficulty includes any special defines that are needed, and then include `coffcode. h'.

Some of the Co targets then also have additional routines in the target source le itself.

For example, `coff-i 960. c' includes `coff/i nternal. h' and `coff/i 960. h'. It then denes a few constants, such as I 960, and includes `coffcode. h'. Since the i960 has complex relocation types, `coff-i 960. c' also includes some code to manipulate the i960 relocs. This code is not in `coffcode. h' because it would not be used by any other target.

3.3.2.2 Coff long section names

In the standard Co object format, section names are limited to the eight bytes available in the s_name eld of the SCNHDR section header structure. The format requires the eld to be NUL-padded, but not necessarily NUL-terminated, so the longest section names permitted are a full eight characters.

The Microsoft PE variants of the Co object le format add an extension to support the use of long section names. This extension is de ned in section 4 of the Microsoft PE/COFF speci cation (rev 8.1). If a section name is too long to t into the section header's s_name eld, it is instead placed into the string table, and the s_name eld is lled with a slash ("/") followed by the ASCII decimal representation of the o set of the full name relative to the string table base.

Note that this implies that the extension can only be used in object les, as executables do not contain a string table. The standard speci es that long section names from objects emitted into executable images are to be truncated.

However, as a GNU extension, BFD can generate executable images that contain a string table and long section names. This would appear to be technically valid, as the standard only says that Co debugging information is deprecated, not forbidden, and in practice it works, although some tools that parse PE les expecting the MS standard format may become confused; 'PEvi ew' is one known example.

The functionality is supported in BFD by code implemented under the control of the macro COFF_LONG_SECTION_NAMES. If not de ned, the format does not support long section names in any way. If de ned, it is used to initialise a ag, _bfd_coff_long_section_names, and a hook function pointer, _bfd_coff_set_long_section_names, in the Co backend data structure. The ag controls the generation of long section names in output BFDs at runtime; if it is false, as it will be by default when generating an executable image, long section names are truncated; if true, the long section names extension is employed. The hook points to a function that allows the value of the ag to be altered at runtime, on formats that support long section names at all; on other formats it points to a stub that returns an error indication.

With input BFDs, the ag is set according to whether any long section names are detected while reading the section headers. For a completely new BFD, the ag is set to the default for the target format. This information can be used by a client of the BFD library when deciding what output format to generate, and means that a BFD that is opened for read

and subsequently converted to a writeable BFD and modi ed in-place will retain whatever format it had on input.

If COFF_LONG_SECTION_NAMES is simply de ned (blank), or is de ned to the value "1",

le in the string table. This pass moves all strings into memory and replaces them with pointers to the strings.

The symbol table is massaged once again, this time to create the canonical table used by the BFD application. Each symbol is inspected in turn, and a decision made (using the scl ass eld) about the various ags to set in the asymbol. See Section 2.7 [Symbols], page 44. The generated canonical table shares strings with the hidden internal symbol table.

Any linenumbers are read from the co le too, and attached to the symbols which own the functions the linenumbers belong to.

3.3.2.5 Symbol writing

Writing a symbol to a co le which didn't come from a co le will lose any debugging information. The asymbol structure remembers the BFD from which the symbol was taken, and on output the back end makes sure that the same destination target as source target is present.

When the symbols have come from a co le then all the debugging information is preserved. Symbol tables are provided for writing to the back end in a vector of pointers to pointers. This allows applications like the linker to accumulate and output large symbol tables without having to do too much byte copying.

This function runs through the provided symbol table and patches each symbol marked as a le place holder (C_FILE) to point to the next le place holder in the list. It also marks each offset eld in the list with the o set from the rst symbol of the current symbol.

Another function of this procedure is to turn the canonical value form of BFD into the form used by co. Internally, BFD expects symbol values to be o sets from a section base; so a symbol physically at 0x120, but in a section starting at 0x100, would have the value 0x20. Co expects symbols to contain their nal value, so symbols have their values changed at this point to re ect their sum with their owning section. This transformation uses the output_section eld of the asymbol 's asection See Section 2.6 [Sections], page 24.

• coff_mangle_symbols

This routine runs though the provided symbol table and uses the o sets generated by the previous pass and the pointers generated when the symbol table was read in to create the structured hierarchy required by co . It changes each pointer to a symbol into the index into the symbol table of the asymbol.

• coff_write_symbols

This routine runs through the symbol table and patches up the symbols from their internal form into the co way, calls the bit twiddlers, and writes out the table to the le.

3.3.2.6 coff_symbol_type

Description

The hidden information for an asymbol is described in a combined entry type:

```
typedef struct coff_ptr_struct
{
    /* Remembers the offset from the first symbol in the file for
    this symbol. Generated by coff_renumber_symbols. */
```

```
unsigned int offset;
 /* Should the value of this symbol be renumbered. Used for
    XCOFF C_BSTAT symbols. Set by coff_slurp_symbol_table. */
 unsigned int fix_value : 1;
 /* Should the tag field of this symbol be renumbered.
     Created by coff_pointerize_aux. */
 unsigned int fix_tag : 1;
 /* Should the endidx field of this symbol be renumbered.
     Created by coff_pointerize_aux. */
 unsigned int fix_end : 1;
 /* Should the x_csect.x_scnlen field be renumbered.
     Created by coff_pointerize_aux. */
 unsigned int fix_scnlen : 1;
 /* Fix up an XCOFF C_BINCL/C_EINCL symbol. The value is the
     index into the line number entries. Set by coff_slurp_symbol_table. */
 unsigned int fix_line : 1;
 /* The container for the symbol structure as read and translated
     from the file. */
 uni on
   union internal_auxent auxent;
   struct internal_syment syment;
 } u:
 /* Selector for the union above. */
bfd_boolean is_sym;
} combined_entry_type;
/* Each canonical asymbol really looks like this: */
typedef struct coff_symbol_struct
 /* The actual symbol which the rest of BFD works with */
 asymbol symbol;
 /* A pointer to the hidden information for this symbol */
 combi ned_entry_type *native;
 /* A pointer to the linenumber information for this symbol */
 struct lineno_cache_entry *lineno;
```

```
/* Have the line numbers been relocated yet ? */
      bfd_boolean_done_lineno;
     } coff_symbol_type;
3.3.2.7 bfd_coff_backend_data
     /* COFF symbol classifications. */
     enum coff_symbol_classification
       /* Global symbol. */
      COFF_SYMBOL_GLOBAL,
       /* Common symbol. */
      COFF SYMBOL COMMON,
       /* Undefined symbol. */
      COFF SYMBOL UNDEFINED,
       /* Local symbol. */
      COFF SYMBOL LOCAL,
       /* PE section symbol. */
      COFF_SYMBOL_PE_SECTION
     };
     typedef asection * (*coff_qc_mark_hook_fn)
       (asection *, struct bfd_link_info *, struct internal_reloc *,
       struct coff_link_hash_entry *, struct internal_syment *);
Special entry points for gdb to swap in co symbol table parts:
     typedef struct
     {
      void (*_bfd_coff_swap_aux_in)
         (bfd *, void *, int, int, int, int, void *);
      void (*_bfd_coff_swap_sym_in)
         (bfd *, void *, void *);
      void (*_bfd_coff_swap_lineno_in)
         (bfd *, void *, void *);

3.3.2.8 Writing relocations

To write relocations, the back end steps though the canonical relocation table and create an internal_reloc. The symbol index to use is removed from the offset eld in the symbol table supplied. The address comes directly from the sum of the section base address and the relocation o set; the type is dug directly from the howto eld. Then the internal_reloc is swapped into the shape of an external_reloc and written out to disk.

3.3.2.9 Reading linenumbers

Creating the linenumber table is done by reading in the entire co linenumber table, and creating another table for internal use.

A co linenumber table is structured so that each function is marked as having a line number of 0. Each line within the function is an o set from the rst line in the function. The base of the line number information for the table is stored in the symbol associated with the function.

Note: The PE format uses line number 0 for a ag indicating a new source le.

The information is copied from the external to the internal table, and each symbol which marks a function is marked by pointing its...

How does this work?

3.3.2.10 Reading relocations

Co relocations are easily transformed into the internal BFD form (arelent).

Reading a correlocation table is done in the following stages:

- Read the entire co relocation table into memory.
- Process each relocation in turn; rst swap it from the external to the internal form.
- Turn the symbol referenced in the relocation's symbol index into a pointer into the canonical symbol table. This table is the same as the one returned by a call to bfd_canonicalize_symtab. The back end will call that routine and save the result if a canonicalization hasn't been done.
- The reloc index is turned into a pointer to a howto structure, in a back end speci c way. For instance, the 386 and 960 use the r_type to directly produce an index into a howto table vector; the 88k subtracts a number from the r_type eld and creates an addend eld.

3.4 ELF backends

BFD support for ELF formats is being worked on. Currently, the best supported back ends are for sparc and i386 (running svr4 or Solaris 2).

Documentation of the internals of the support code still needs to be written. The code is changing quickly enough that we haven't bothered yet.

3.5 mmo backend

The mmo object format is used exclusively together with Professor Donald E. Knuth's educational 64-bit processor MMIX. The simulator mmix which is available at http://mmix.cs.hm.edu/src/index.html understands this format. That package also includes a combined assembler and linker called mmixal. The mmo format has no advantages feature-wise compared to e.g. ELF. It is a simple non-relocatable object format with no support for archives or debugging information, except for symbol value information and line numbers (which is not yet implemented in BFD). See http://mmix.cs.hm.edu/formore information about MMIX. The ELF format is used for intermediate object les in the BFD implementation.

3.5.1 File layout

The mmo le contents is not partitioned into named sections as with e.g. ELF. Memory areas is formed by specifying the location of the data that follows. Only the memory area `0x0000...00' to `0x01ff...ff' is executable, so it is used for code (and constants) and the area `0x2000...00' to `0x20ff...ff' is used for writable data. See Section 3.5.3 [mmo section mapping], page 210.

There is provision for specifying \special data" of 65536 di erent types. We use type 80 (decimal), arbitrarily chosen the same as the ELF e_machi ne number for MMIX, Iling it with section information normally found in ELF objects. See Section 3.5.3 [mmo section mapping], page 210.

Contents is entered as 32-bit words, xor:ed over previous contents, always zero-initialized. A word that starts with the byte `0x98' forms a command called a `l opcode', where the

next byte distinguished between the thirteen lopcodes. The two remaining bytes, called the `Y' and `Z' elds, or the `YZ' eld (a 16-bit big-endian number), are used for various purposes di erent for each lopcode. As documented in http://mmix.cs.hm.edu/doc/mmixal.pdf, the lopcodes are:

I op_quote

0x98000001. The next word is contents, regardless of whether it starts with 0x98 or not.

lop_loc 0x9801YYZZ, where `Z' is 1 or 2. This is a location directive, setting the location for the next data to the next 32-bit word (for Z=1) or 64-bit word (for Z=2), plus $Y*2^56$. Normally `Y' is 0 for the text segment and 2 for the data segment. Beware that the low bits of non- tetrabyte-aligned values are silently discarded when being automatically incremented and when storing contents (in contrast to e.g. its use as current location when followed by lop_ xo et al before the next possibly-quoted tetrabyte contents).

lop_skip 0x9802YYZZ. Increase the current location by `YZ' bytes.

lop_fi xo 0x9803YYZZ, where `Z' is 1 or 2. Store the current location as 64 bits into the location pointed to by the next 32-bit (Z=1) or 64-bit (Z=2) word, plus $Y*2^56$.

lop_fi xr 0x9804YYZZ. `YZ' is stored into the current location plus 2 - 4 * YZ.

lop_fixrx

0x980500ZZ. 'Z' is 16 or 24. A value 'L' derived from the following 32-bit word are used in a manner similar to 'YZ' in lop_x xr: it is xor:ed into the current location minus 4*L. The rst byte of the word is 0 or 1. If it is 1, then $L = (lowest24bitsofword) - 2^Z$, if 0, then L = (lowest24bitsofword).

lop_file 0x9806YYZZ. `Y' is the le number, `Z' is count of 32-bit words. Set the le number to `Y' and the line counter to 0. The next Z*4 bytes contain the le name, padded with zeros if the count is not a multiple of four. The same `Y' may occur multiple times, but `Z' must be 0 for all but the rst occurrence.

I op_line Ox9807YYZZ. `YZ' is the line number. Together with lop_le, it forms the source location for the next 32-bit word. Note that for each non-lopcode 32-bit word, line numbers are assumed incremented by one.

Other types than 80, (or type 80 with a content that does not parse) is stored in sections named . MMI X. spec_data. n where n is the `YZ'-type. The ags for such a sections say not to allocate or load the data. The vma is 0. Contents of multiple occurrences of special data n is concatenated to the data of the previous lop_spec ns. The location in data or code at which the lop_spec occurred is lost.

lop_pre 0x980901ZZ. The rst lopcode in a le. The `Z' eld forms the length of header information in 32-bit words, where the rst word tells the time in seconds since `00: 00: 00 GMT Jan 1 1970'.

lop_post 0x980a00ZZ. Z>32. This lopcode follows after all content-generating lopcodes in a program. The `Z' eld denotes the value of `rG' at the beginning of the program. The following 256-Z big-endian 64-bit words are loaded into global registers `\$G' . . . `\$255'.

lop_stab 0x980b0000. The next-to-last lopcode in a program. Must follow immediately after the lop_post lopcode and its data. After this lopcode follows all symbols in a compressed format (see Section 3.5.2 [Symbol-table], page 208).

Note that the lopcode " xups"; lop_fi xr, lop_fi xrx and lop_fi xo are not generated by BFD, but are handled. They are generated by mmi xal.

This trivial one-label, one-instruction le:

```
: Main TRAP 1, 2, 3
```

can be represented this way in mmo:

```
0x98090101 - lop_pre, one 32-bit word with timestamp.
<timestamp>
0x98010002 - lop_loc, text segment, using a 64-bit address.
             Note that mmixal does not emit this for the file above.
0x00000000 - Address, high 32 bits.
0x00000000 - Address, low 32 bits.
0x98060002 - lop_file, 2 32-bit words for file-name.
0x74657374 - "test"
0x2e730000 - ".s\0\0"
0x98070001 - lop_line, line 1.
0x00010203 - TRAP 1, 2, 3
0x980a00ff - lop_post, setting $255 to 0.
0x00000000
0x00000000
0x980b0000 - lop_stab for ":Main" = 0, serial 1.
             See Section 3.5.2 [Symbol-table], page 208.
0x203a4040
0x10404020
0x4d206120
0x69016e00
0x81000000
0x980c0005 - lop end; symbol table contained five 32-bit words.
```

3.5.2 Symbol table format

From mmixal.w (or really, the generated mmixal.tex) in the MMIXware package which also contains the mmi x simulator: \Symbols are stored and retrieved by means of a `ternary search trie', following ideas of Bentley and Sedgewick. (See ACM{SIAM Symp. on Discrete Algorithms `8' (1997), 360{369; R.Sedgewick, `Al gori thms in C' (Reading, Mass. Addison{Wesley, 1998), `15. 4'.) Each trie node stores a character, and there are branches to subtries for the cases where a given character is less than, equal to, or greater than the

character in the trie. There also is a pointer to a symbol table entry if a symbol ends at the current node."

So it's a tree encoded as a stream of bytes. The stream of bytes acts on a single virtual global symbol, adding and removing characters and signalling complete symbol points. Here, we read the stream and create symbols at the completion points.

First, there's a control byte m. If any of the listed bits in m is nonzero, we execute what stands at the right, in the listed order:

(MMO3_LEFT)

0x40 - Traverse left trie. (Read a new command byte and recurse.)

(MMO3_SYMBITS)

Ox2f - Read the next byte as a character and store it in the current character position; increment character position. Test the bits of m:

(MMO3_WCHAR)

0x80 - The character is 16-bit (so read another byte, merge into current character.

(MMO3_TYPEBITS)

Oxf - We have a complete symbol; parse the type, value and serial number and do what should be done with a symbol. The type and length information is in j = (m & Oxf).

(MMO3 REGQUAL BITS)

j <= 8: An absolute symbol. Read j bytes as the big-endian number the symbol equals. A j = 2 with two zero bytes denotes an unknown symbol.

j > 8: As with j <= 8, but add (0x20 << 56) to the value in the following j - 8 bytes.

Then comes the serial number, as a variant of uleb128, but better named ubeb128: Read bytes and shift the previous value left 7 (multiply by 128). Add in the new byte, repeat until a byte has bit 7 set. The serial number is the computed value minus 128.

(MMO3_MIDDLE)

0x20 - Traverse middle trie. (Read a new command byte

```
and recurse.) Decrement character position.
      (MMO3_RIGHT)
      Ox10 - Traverse right trie. (Read a new command byte and
             recurse.)
Let's look again at the lop_stab for the trivial le (see Section 3.5.1 [File layout], page 206).
      0x980b0000 - lop stab for ": Main" = 0, serial 1.
      0x203a4040
      0x10404020
      0x4d206120
      0x69016e00
      0x81000000
This forms the trivial trie (note that the path between \:" and \M" is redundant):
      203a
      40
      40
      10
      40
      40
            "M"
      204d
            "a"
      2061
      2069
            "i"
      016e "n" is the last character in a full symbol, and
            with a value represented in one byte.
            The value is 0.
      00
      81
            The serial number is 1.
```

3.5.3 mmo section mapping

The implementation in BFD uses special data type 80 (decimal) to encapsulate and describe named sections, containing e.g. debug information. If needed, any datum in the encapsulation will be quoted using lop_quote. First comes a 32-bit word holding the number of 32-bit words containing the zero-terminated zero-padded segment name. After the name there's a 32-bit word holding ags describing the section type. Then comes a 64-bit big-endian word with the section length (in bytes), then another with the section start address. Depending on the type of section, the contents might follow, zero-padded to 32-bit boundary. For a loadable section (such as data or code), the contents might follow at some later point, not necessarily immediately, as a lop_loc with the same start address as in the section description, followed by the contents. This in e ect forms a descriptor that must be emitted before the actual contents. Sections described this way must not overlap.

For areas that don't have such descriptors, synthetic sections are formed by BFD. Consecutive contents in the two memory areas `0x0000...00' to `0x01ff...ff' and `0x2000...00' to `0x20ff...ff' are entered in sections named . text and . data respectively. If an area is not otherwise described, but would together with a neighboring lower area be less than `0x40000000' bytes long, it is joined with the lower area and the gap is zero- Iled. For other cases, a new section is formed, named . MMI X. sec. \mathbf{n} . Here, \mathbf{n} is a number, a running count through the mmo le, starting at 0.

```
A loadable section speci ed as:
      . section secname, "ax"
      TETRA 1, 2, 3, 4, -1, -2009
      BYTE 80
and linked to address `0x4', is represented by the sequence:
      0x98080050 - lop_spec 80
      0x00000002 - two 32-bit words for the section name
      0x7365636e - "secn"
      0x616d6500 - "ame\0"
      0x00000033 - flags CODE, READONLY, LOAD, ALLOC
      0x00000000 - high 32 bits of section length
      0x0000001c - section length is 28 bytes; 6 * 4 + 1 + alignment to 32 bits
      0x00000000 - high 32 bits of section address
      0x00000004 - section address is 4
      0x98010002 - 64 bits with address of following data
      0x00000000 - high 32 bits of address
      0x00000004 - Iow 32 bits: data starts at address 4
      0x00000001 - 1
      0x00000002 - 2
      0x00000003 - 3
      0x00000004 - 4
      0xfffffff - -1
      0xfffff827 - -2009
      0x50000000 - 80 as a byte, padded with zeros.
Note that the lop_spec wrapping does not include the section contents. Compare this to a
non-loaded section speci ed as:
      .section thirdsec
      TETRA 200001, 100002
      BYTE 38, 40
This, when linked to address `0x2000000000001c', is represented by:
      0x98080050 - lop_spec 80
      0x00000002 - two 32-bit words for the section name
      0x7365636e - "thir"
      0x616d6500 - "dsec"
      0x00000010 - flag READONLY
      0x00000000 - high 32 bits of section length
      0x0000000c - section length is 12 bytes; 2 * 4 + 2 + alignment to 32 bits
      0x20000000 - high 32 bits of address
      0x0000001c - low 32 bits of address 0x20000000000001c
      0x00030d41 - 200001
      0x000186a2 - 100002
      0x26280000 - 38, 40 as bytes, padded with zeros
For the latter example, the section contents must not be loaded in memory, and is therefore
```

For the latter example, the section contents must not be loaded in memory, and is therefore specified as part of the special data. The address is usually unimportant but might provide information for e.g. the DWARF 2 debugging format.

Version 1.3, 3 November 2008

Copyright © 2000, 2001, 2002, 2007, 2008 Free Software Foundation, Inc. http://fsf.org/

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

0. PREAMBLE

The purpose of this License is to make a manual, textbook, or other functional and useful document *free* in the sense of freedom: to assure everyone the e ective freedom to copy and redistribute it, with or without modifying it, either commercially or non-commercially. Secondarily, this License preserves for the author and publisher a way to get credit for their work, while not being considered responsible for modi cations made by others.

This License is a kind of \copyleft", which means that derivative works of the document must themselves be free in the same sense. It complements the GNU General Public License, which is a copyleft license designed for free software.

We have designed this License in order to use it for manuals for free software, because free software needs free documentation: a free program should come with manuals providing the same freedoms that the software does. But this License is not limited to software manuals; it can be used for any textual work, regardless of subject matter or whether it is published as a printed book. We recommend this License principally for works whose purpose is instruction or reference.

1. APPLICABILITY AND DEFINITIONS

This License applies to any manual or other work, in any medium, that contains a notice placed by the copyright holder saying it can be distributed under the terms of this License. Such a notice grants a world-wide, royalty-free license, unlimited in duration, to use that work under the conditions stated herein. The \Document", below, refers to any such manual or work. Any member of the public is a licensee, and is addressed as \you". You accept the license if you copy, modify or distribute the work in a way requiring permission under copyright law.

A \Modi ed Version" of the Document means any work containing the Document or a portion of it, either copied verbatim, or with modi cations and/or translated into another language.

A \Secondary Section" is a named appendix or a front-matter section of the Document that deals exclusively with the relationship of the publishers or authors of the Document to the Document's overall subject (or to related matters) and contains nothing that could fall directly within that overall subject. (Thus, if the Document is in part a textbook of mathematics, a Secondary Section may not explain any mathematics.) The relationship could be a matter of historical connection with the subject or with related matters, or of legal, commercial, philosophical, ethical or political position regarding them.

The \Invariant Sections" are certain Secondary Sections whose titles are designated, as being those of Invariant Sections, in the notice that says that the Document is released under this License. If a section does not the above denition of Secondary then it is

not allowed to be designated as Invariant. The Document may contain zero Invariant Sections. If the Document does not identify any Invariant Sections then there are none.

The \Cover Texts" are certain short passages of text that are listed, as Front-Cover Texts or Back-Cover Texts, in the notice that says that the Document is released under this License. A Front-Cover Text may be at most 5 words, and a Back-Cover Text may be at most 25 words.

A \Transparent" copy of the Document means a machine-readable copy, represented in a format whose speci cation is available to the general public, that is suitable for revising the document straightforwardly with generic text editors or (for images composed of pixels) generic paint programs or (for drawings) some widely available drawing editor, and that is suitable for input to text formatters or for automatic translation to a variety of formats suitable for input to text formatters. A copy made in an otherwise Transparent le format whose markup, or absence of markup, has been arranged to thwart or discourage subsequent modi cation by readers is not Transparent. An image format is not Transparent if used for any substantial amount of text. A copy that is not \Transparent" is called \Opaque".

Examples of suitable formats for Transparent copies include plain ASCII without markup, Texinfo input format, LaTEX input format, SGML or XML using a publicly available DTD, and standard-conforming simple HTML, PostScript or PDF designed for human modi cation. Examples of transparent image formats include PNG, XCF and JPG. Opaque formats include proprietary formats that can be read and edited only by proprietary word processors, SGML or XML for which the DTD and/or processing tools are not generally available, and the machine-generated HTML, PostScript or PDF produced by some word processors for output purposes only.

The \Title Page" means, for a printed book, the title page itself, plus such following pages as are needed to hold, legibly, the material this License requires to appear in the title page. For works in formats which do not have any title page as such, \Title Page" means the text near the most prominent appearance of the work's title, preceding the beginning of the body of the text.

The \publisher" means any person or entity that distributes copies of the Document to the public.

A section \Entitled XYZ" means a named subunit of the Document whose title either is precisely XYZ or contains XYZ in parentheses following text that translates XYZ in another language. (Here XYZ stands for a speci-c section name mentioned below, such as \Acknowledgements", \Dedications", \Endorsements", or \History".) To \Preserve the Title" of such a section when you modify the Document means that it remains a section \Entitled XYZ" according to this de nition.

The Document may include Warranty Disclaimers next to the notice which states that this License applies to the Document. These Warranty Disclaimers are considered to be included by reference in this License, but only as regards disclaiming warranties: any other implication that these Warranty Disclaimers may have is void and has no e ect on the meaning of this License.

2. VERBATIM COPYING

You may copy and distribute the Document in any medium, either commercially or noncommercially, provided that this License, the copyright notices, and the license

notice saying this License applies to the Document are reproduced in all copies, and that you add no other conditions whatsoever to those of this License. You may not use technical measures to obstruct or control the reading or further copying of the copies you make or distribute. However, you may accept compensation in exchange for copies. If you distribute a large enough number of copies you must also follow the conditions in section 3.

You may also lend copies, under the same conditions stated above, and you may publicly display copies.

3. COPYING IN QUANTITY

If you publish printed copies (or copies in media that commonly have printed covers) of the Document, numbering more than 100, and the Document's license notice requires Cover Texts, you must enclose the copies in covers that carry, clearly and legibly, all these Cover Texts: Front-Cover Texts on the front cover, and Back-Cover Texts on the back cover. Both covers must also clearly and legibly identify you as the publisher of these copies. The front cover must present the full title with all words of the title equally prominent and visible. You may add other material on the covers in addition. Copying with changes limited to the covers, as long as they preserve the title of the Document and satisfy these conditions, can be treated as verbatim copying in other respects.

If the required texts for either cover are too voluminous to t legibly, you should put the rst ones listed (as many as t reasonably) on the actual cover, and continue the rest onto adjacent pages.

If you publish or distribute Opaque copies of the Document numbering more than 100, you must either include a machine-readable Transparent copy along with each Opaque copy, or state in or with each Opaque copy a computer-network location from which the general network-using public has access to download using public-standard network protocols a complete Transparent copy of the Document, free of added material. If you use the latter option, you must take reasonably prudent steps, when you begin distribution of Opaque copies in quantity, to ensure that this Transparent copy will remain thus accessible at the stated location until at least one year after the last time you distribute an Opaque copy (directly or through your agents or retailers) of that edition to the public.

It is requested, but not required, that you contact the authors of the Document well before redistributing any large number of copies, to give them a chance to provide you with an updated version of the Document.

4. MODIFICATIONS

You may copy and distribute a Modi ed Version of the Document under the conditions of sections 2 and 3 above, provided that you release the Modi ed Version under precisely this License, with the Modi ed Version Illing the role of the Document, thus licensing distribution and modi cation of the Modi ed Version to whoever possesses a copy of it. In addition, you must do these things in the Modi ed Version:

A. Use in the Title Page (and on the covers, if any) a title distinct from that of the Document, and from those of previous versions (which should, if there were any, be listed in the History section of the Document). You may use the same title as a previous version if the original publisher of that version gives permission.

- B. List on the Title Page, as authors, one or more persons or entities responsible for authorship of the modi cations in the Modi ed Version, together with at least ve of the principal authors of the Document (all of its principal authors, if it has fewer than ve), unless they release you from this requirement.
- C. State on the Title page the name of the publisher of the Modi ed Version, as the publisher.
- D. Preserve all the copyright notices of the Document.
- E. Add an appropriate copyright notice for your modi cations adjacent to the other copyright notices.
- F. Include, immediately after the copyright notices, a license notice giving the public permission to use the Modi ed Version under the terms of this License, in the form shown in the Addendum below.
- G. Preserve in that license notice the full lists of Invariant Sections and required Cover Texts given in the Document's license notice.
- H. Include an unaltered copy of this License.
- I. Preserve the section Entitled \History", Preserve its Title, and add to it an item stating at least the title, year, new authors, and publisher of the Modi ed Version as given on the Title Page. If there is no section Entitled \History" in the Document, create one stating the title, year, authors, and publisher of the Document as given on its Title Page, then add an item describing the Modi ed Version as stated in the previous sentence.
- J. Preserve the network location, if any, given in the Document for public access to a Transparent copy of the Document, and likewise the network locations given in the Document for previous versions it was based on. These may be placed in the \History" section. You may omit a network location for a work that was published at least four years before the Document itself, or if the original publisher of the version it refers to gives permission.
- K. For any section Entitled \Acknowledgements" or \Dedications", Preserve the Title of the section, and preserve in the section all the substance and tone of each of the contributor acknowledgements and/or dedications given therein.
- L. Preserve all the Invariant Sections of the Document, unaltered in their text and in their titles. Section numbers or the equivalent are not considered part of the section titles.
- M. Delete any section Entitled \Endorsements". Such a section may not be included in the Modi ed Version.
- N. Do not retitle any existing section to be Entitled \Endorsements" or to con ict in title with any Invariant Section.
- O. Preserve any Warranty Disclaimers.

If the Modi ed Version includes new front-matter sections or appendices that qualify as Secondary Sections and contain no material copied from the Document, you may at your option designate some or all of these sections as invariant. To do this, add their titles to the list of Invariant Sections in the Modi ed Version's license notice. These titles must be distinct from any other section titles.

You may add a section Entitled \Endorsements", provided it contains nothing but endorsements of your Modi ed Version by various parties | for example, statements of peer review or that the text has been approved by an organization as the authoritative de nition of a standard.

You may add a passage of up to ve words as a Front-Cover Text, and a passage of up to 25 words as a Back-Cover Text, to the end of the list of Cover Texts in the Modi ed Version. Only one passage of Front-Cover Text and one of Back-Cover Text may be added by (or through arrangements made by) any one entity. If the Document already includes a cover text for the same cover, previously added by you or by arrangement made by the same entity you are acting on behalf of, you may not add another; but you may replace the old one, on explicit permission from the previous publisher that added the old one.

The author(s) and publisher(s) of the Document do not by this License give permission to use their names for publicity for or to assert or imply endorsement of any Modi ed Version.

5. COMBINING DOCUMENTS

You may combine the Document with other documents released under this License, under the terms de ned in section 4 above for modi ed versions, provided that you include in the combination all of the Invariant Sections of all of the original documents, unmodi ed, and list them all as Invariant Sections of your combined work in its license notice, and that you preserve all their Warranty Disclaimers.

The combined work need only contain one copy of this License, and multiple identical Invariant Sections may be replaced with a single copy. If there are multiple Invariant Sections with the same name but di erent contents, make the title of each such section unique by adding at the end of it, in parentheses, the name of the original author or publisher of that section if known, or else a unique number. Make the same adjustment to the section titles in the list of Invariant Sections in the license notice of the combined work.

In the combination, you must combine any sections Entitled \History" in the various original documents, forming one section Entitled \History"; likewise combine any sections Entitled \Acknowledgements", and any sections Entitled \Dedications". You must delete all sections Entitled \Endorsements."

6. COLLECTIONS OF DOCUMENTS

You may make a collection consisting of the Document and other documents released under this License, and replace the individual copies of this License in the various documents with a single copy that is included in the collection, provided that you follow the rules of this License for verbatim copying of each of the documents in all other respects.

You may extract a single document from such a collection, and distribute it individually under this License, provided you insert a copy of this License into the extracted document, and follow this License in all other respects regarding verbatim copying of that document.

7. AGGREGATION WITH INDEPENDENT WORKS

A compilation of the Document or its derivatives with other separate and independent documents or works, in or on a volume of a storage or distribution medium, is called

an \aggregate" if the copyright resulting from the compilation is not used to limit the legal rights of the compilation's users beyond what the individual works permit. When the Document is included in an aggregate, this License does not apply to the other works in the aggregate which are not themselves derivative works of the Document.

If the Cover Text requirement of section 3 is applicable to these copies of the Document, then if the Document is less than one half of the entire aggregate, the Document's Cover Texts may be placed on covers that bracket the Document within the aggregate, or the electronic equivalent of covers if the Document is in electronic form. Otherwise they must appear on printed covers that bracket the whole aggregate.

8. TRANSLATION

Translation is considered a kind of modi cation, so you may distribute translations of the Document under the terms of section 4. Replacing Invariant Sections with translations requires special permission from their copyright holders, but you may include translations of some or all Invariant Sections in addition to the original versions of these Invariant Sections. You may include a translation of this License, and all the license notices in the Document, and any Warranty Disclaimers, provided that you also include the original English version of this License and the original versions of those notices and disclaimers. In case of a disagreement between the translation and the original version of this License or a notice or disclaimer, the original version will prevail.

If a section in the Document is Entitled \Acknowledgements", \Dedications", or \History", the requirement (section 4) to Preserve its Title (section 1) will typically require changing the actual title.

9. TERMINATION

You may not copy, modify, sublicense, or distribute the Document except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, or distribute it is void, and will automatically terminate your rights under this License.

However, if you cease all violation of this License, then your license from a particular copyright holder is reinstated (a) provisionally, unless and until the copyright holder explicitly and nally terminates your license, and (b) permanently, if the copyright holder fails to notify you of the violation by some reasonable means prior to 60 days after the cessation.

Moreover, your license from a particular copyright holder is reinstated permanently if the copyright holder noti es you of the violation by some reasonable means, this is the rst time you have received notice of violation of this License (for any work) from that copyright holder, and you cure the violation prior to 30 days after your receipt of the notice.

Termination of your rights under this section does not terminate the licenses of parties who have received copies or rights from you under this License. If your rights have been terminated and not permanently reinstated, receipt of a copy of some or all of the same material does not give you any rights to use it.

10. FUTURE REVISIONS OF THIS LICENSE

The Free Software Foundation may publish new, revised versions of the GNU Free Documentation License from time to time. Such new versions will be similar in spirit

to the present version, but may di er in detail to address new problems or concerns. See http://www.gnu.org/copyleft/.

Each version of the License is given a distinguishing version number. If the Document speci es that a particular numbered version of this License \or any later version" applies to it, you have the option of following the terms and conditions either of that speci ed version or of any later version that has been published (not as a draft) by the Free Software Foundation. If the Document does not specify a version number of this License, you may choose any version ever published (not as a draft) by the Free Software Foundation. If the Document speci es that a proxy can decide which future versions of this License can be used, that proxy's public statement of acceptance of a version permanently authorizes you to choose that version for the Document.

11. RELICENSING

\Massive Multiauthor Collaboration Site" (or \MMC Site") means any World Wide Web server that publishes copyrightable works and also provides prominent facilities for anybody to edit those works. A public wiki that anybody can edit is an example of such a server. A \Massive Multiauthor Collaboration" (or \MMC") contained in the site means any set of copyrightable works thus published on the MMC site.

\CC-BY-SA" means the Creative Commons Attribution-Share Alike 3.0 license published by Creative Commons Corporation, a not-for-pro t corporation with a principal place of business in San Francisco, California, as well as future copyleft versions of that license published by that same organization.

\Incorporate" means to publish or republish a Document, in whole or in part, as part of another Document.

An MMC is \eligible for relicensing" if it is licensed under this License, and if all works that were rst published under this License somewhere other than this MMC, and subsequently incorporated in whole or in part into the MMC, (1) had no cover texts or invariant sections, and (2) were thus incorporated prior to November 1, 2008.

The operator of an MMC Site may republish an MMC contained in the site under CC-BY-SA on the same site at any time before August 1, 2009, provided the MMC is eligible for relicensing.

ADDENDUM: How to use this License for your documents

To use this License in a document you have written, include a copy of the License in the document and put the following copyright and license notices just after the title page:

Copyright (C) year your name. Permission is granted to copy, distribute and/or modify this document under the terms of the GNU Free Documentation License, Version 1.3 or any later version published by the Free Software Foundation; with no Invariant Sections, no Front-Cover Texts, and no Back-Cover Texts. A copy of the license is included in the section entitled ``GNU Free Documentation License''.

If you have Invariant Sections, Front-Cover Texts and Back-Cover Texts, replace the \with...Texts." line with this:

with the Invariant Sections being *list their titles*, with the Front-Cover Texts being *list*, and with the Back-Cover Texts being *list*.

If you have Invariant Sections without Cover Texts, or some other combination of the three, merge those two alternatives to suit the situation.

If your document contains nontrivial examples of program code, we recommend releasing these examples in parallel under your choice of free software license, such as the GNU General Public License, to permit their use in free software.
